Editorial

July Fourth, 1941

Once again, Independence Day Ironically, such a day *was* celebrated in Czechoslovakia, October 26, in Poland, May 3, in Norway, May 17, in Belgium, July 21, in France, July 14, in Greece, March 25 Independence is something you have to do something about, you can't take it out in talk and parades or by shooting off firecrackers Independence is priceless only in orations We said that a year ago¹ Now we repeat it Actually, as the above-mentioned countries have found out, the price is a fearful one It is going up! It is a price that is not subject to political or economic controls It is imposed from without and must be paid in blood, sweat of human labor, agony of body and mind—now!

American medicine is prepared to pay it Dr Frank Lahey, of Boston, incoming president of the A M A. said in Cleveland, on June 3 "My own opinion, and I believe that it is my duty to express it, is that we are already committed to a position, whether we like it or not I myself like it We should arrive at a conviction concerning isolation Is it right? It is my conviction that it is not I prefer destruction if it need be to survival in cowering terror Give me positive commitment rather than compromising, unsatisfying safety "

In such a belief did Benjamin Rush, M D, set his signature to paper in 1776 Now, 164 years later, Dr Lahey spoke for a united medical profession when he said "We shall still have ourselves to live with

I do not believe there is a safe course

It is my conviction that a dangerous course has real advantages" It has the real advantage that it is positive, it has the real advantage that it is bold in the conviction that it is right! Such a course can command the loyalty of men and women, can stir vigorously the fires of devotion now too long banked with the bitter ashes of complacency and like to smother altogether amidst the clinkers and dross of a fatuous, futile, and chimerical security

This JOURNAL is squarely behind Dr Lahey and the President of the United States We believe with Dr Lahey that we must "establish what is to be the policy of this Nation as relates to the war situation there is nothing, and in our history never has been anything, which will influence the future of America more than the nature of this decision The real urgency of this situation is that we need outstandingly a dispersal of internal conflicts and, regardless of what we have said or thought, there must be unanimity " United we stand, divided we fall

Industrial Physicians Needed

"The Army," says the *New York Times* editorially,¹ "has drafted its quota of physicians, with the result that there is some reason to worry how the large industrial centers will fare." Both medicine and industry are being mobilized, as the *Times* observes, the expanding army and expanding industry are making vast demands upon the personnel of mobilized medicine. It is to be remembered that the military services require about five times as many medical men per one thousand troops as are required in civilian practice.

In the February 1, 1941, issue of the *JOURNAL* we commented editorially upon the shortages in trained medical personnel to meet the needs of industrial practice under the heading, "Industrial Health and the Defense Program." In this editorial we called for "an expanded program of instruction in industrial hygiene," and said further "If the industrial health program is to become an effective measure for national defense it must be coordinated with the general plan and be adequately financed without loss of time." Some progress has been made undoubtedly but, even so, the medical service to workers in industry must be realistically approached.

"A small number of universities are now providing training courses for industrial hygienists²

"Most notable of these is the one at Harvard School of Public Health under the direction of Philip Drinker, professor of industrial hygiene, which has been supplying well-trained men to the field for many years. Others are the University of Pennsylvania Medical School, Department of Public Health and Hygiene, where industrial hygiene engineering is under the direction of Professor Theodore Hatch. Professor Donald E. Cummings, director of the Division of Industrial Hygiene, University of Colorado Medical School, is amply qualified through his practical accomplishments

in this field for training industrial hygiene engineers. The University of Pittsburgh Medical School and Johns Hopkins University have set up curricula, the latter largely for physicians in public health administration courses. Other institutions, the University of Michigan, for example, have also been interesting themselves in this field.²

"The Division of Industrial Hygiene of the National Institute of Health has presented brief courses in industrial hygiene over the last five years and has directed in-service training in many of the state units. The National Conference of Governmental Industrial Hygienists, sponsored by the United States Public Health Service, has through its annual meetings been doing much in furthering the training of industrial hygiene engineers attached to federal, state, and municipal departments."²

"We are drilling an Army of about 1,400,000 young men, with the prospect that the number may reach 4,000,000 if the international situation does not improve. This Army is medically cared for by regimental doctors who must practice a kind of 'socialized' medicine. Because soldiers are in the flower of life, because they are under more or less constant medical supervision, they are bound to make a commendable health record. But what of the industrial workers? Committees of able physicians have been formed by the Government to frame plans for the maintenance of industrial health. They may give advice, but they have no authority. Admirable as the medical plans are, they receive neither from the Government nor the public the wholehearted support that they deserve.¹

"It is easy enough to foretell what is likely to happen a year or so hence. The health record of the Army will be held up for admiration, that of industrial centers for condemnation. Inevitable and unjust comparisons will be made between Army 'socialized' medicine and the kind of medicine that physicians were able to give workers. If we are to avoid the kind

¹ *New York Times* editorial June 6, 1941

² *Industrial Hygiene* 10 No. 5 198 (May) 1941

of political medicine that physicians fear, we need a more realistic approach to the problem of national health and a program of action that will win popular support"¹

The Problem of the Deferred Draftee

Behind the armed forces lies the shadowland of the civilian population. Within this land, the target of attack and disorganization by propaganda and the tactics of terror in modern warfare, wanders the rejected draftee. He is at loose ends, unwanted, doomed to go to and fro in the earth, and to walk up and down in it a pariah, until, like Job, he be tempted to open his mouth and say "Let the day perish wherein I was born, and the night in which it was said, There is a man child conceived."

As for that night, let darkness seize upon it, let it not be joined unto the days of the year, let it not come into the number of the months for his grief was very great."

Seemingly despised, rejected, many men with feelings of insecurity and inferiority will shortly come to inhabit that civilian shadowland, fair prey for the propagandist, the irresponsible racketeer union agitator, the dispenser of antisocial doctrines, and the medical quack. The physical and mental problems of these deferred men are the joint responsibility of the physician who will care for them tactfully and sympathetically and of society which must make provision for their re-education in self-respect. For the solution of the difficulties of the deferred men is a matter intimately bound up in the maintenance of civilian morale.

This important sequel to the training program currently in effect is discussed in a paper on page 1339 of this issue by

Lowell S. Selling, M.D., entitled "The Mental Hygiene Aspect of the Deferred Draftee." Leadership in coping realistically with these and many other medical problems associated with the preparedness program is essential. The American Medical Association has realized this and has endeavored for some time to exercise its unquestionably authoritative influence to have created a centralized agency in the government to deal with the problems of medicine. This JOURNAL is also of the opinion that this should be done now—without delay. As far as we are aware, nothing has been accomplished, in spite of the attempts that have been made to stress its importance to the administration.

Whether the trouble arises from stupidity, incomprehension, indifference, or ignorance we have no means of finding out. But neglect of a proper and just consideration of such recommendations has a way of imposing costly penalties and tragic consequences. Perhaps in time, if there be time, the Federal Social Security Administration will be designated as such a centralized agency. The maintenance of civilian morale would certainly seem to us to be a step in the direction of avoiding a rapidly mounting quota of antisocial insecurity, agitated by persons of questionable mental and emotional stability. We cannot urge again too strongly that the Government, give this matter immediate and purposeful consideration—*now*.

We Quote

Probably one of the best answers to the protagonists of the several forms of socialized medicine is the address delivered at the Harvard Medical School by Professor Austrian of Johns Hopkins University.¹ To do

justice, the entire speech should be reprinted but the following excerpts will emphasize the wisdom of retaining our present form of medical service.

"The study of a patient should be skillful and intelligently complete, not needlessly comprehensive. Routine performance of

¹ Austrian, A. R. *New England J. Med.* 223: 695 (1940).

needless tests indicates a lack of skillful observation and thinking, dulls clinical acumen, penalizes the patients, wastes time and material, and gives the public an incorrect view of the cost of sound medical care.

"In the course of time, many sciences have become the assistants of medicine, so that diagnosis and treatment are established on a surer foundation. Sometimes, it has seemed, these helpers have altered the perspective and dimmed the aims of the helped by placing too much emphasis on the objective aspects of disease and too little on the subjective."

How is it possible to avoid, under any form of regimented medicine, the waste of time and material, the undue stress upon and abuse of laboratory aids, and the neglect to apply keen clinical judgment? "The engineer, the mechanic, and the artist of every sort work with materials of known composition, but you as a physician deal with a structure more complex, less understood, with a great many parts, all of which are not only self-wearing but must be self-repairing, and the

evidence for the defects of which may be quite elusive. To find the clues and to procure the incriminating evidence of damage will often tax you more than it does a detective."

Each year's crop of interns necessitates reiteration of admonitions against routinely ordering x-rays, hematologic studies, basal metabolism, and the numerous other tests that only an intern can think up on the spur of the moment for a new admission *before he has examined the patient completely*. What will happen to the *quality* and the *cost* of medical care under governmental supervision when the patient feels, to put it in the vernacular, that he is "entitled to the works"? Of more importance, what will happen when "observation, still the most informative of all clinical methods, seems so simple that it is practiced too little? To the trained eye, all that is seen is pregnant with information. There is opened a vista of diagnostic, therapeutic, and even prognostic data that no other single procedure could reveal."

Giardiasis

Giardiasis is an infection of the intestinal tract by the parasite *Giardia lamblia*. Its incidence in the United States varies with geographic location and it is more prevalent in the southern zones. Nutter, Rodaniche, and Palmer,¹ in their studies conducted in Chicago, found the incidence to be 1.5 per cent, although they state that this is considerably lower than usually found in the North Temperate Zone.

The symptoms presented are diarrhea, abdominal pain and flatus, fatigue, bloody stools, insomnia, vertigo, and loss of weight. In children, giardiasis may simulate celiac disease.² Duodenal drainage by the Lyon technic, with samples taken at various levels, showed the vegetative forms of *lamblia* in all but 2 cases of Nutter and his co-workers. The stools all showed the protozoan. The disease appears to be more predominant in men and occurs most frequently in the third decade of life.

The controversy over the pathogenicity of this parasite was dispelled with the introduction, in 1937, of atabrin dihydrochloride as

an effective lamblacide.³ The value of this drug in giardiasis has been confirmed both here and abroad. Nutter, *et al*, administered 0.1 Gm. of atabrin dihydrochloride three times daily by mouth for a period of five days. This method of therapy successfully freed all patients of their infection, and the diarrhea invariably ceased. The *Giardia* cysts often disappeared as early as the third day. The toxic effect of the drug is slight and there were no severe reactions from its use. It must be noted that atabrin apparently has no effect upon other parasites in the intestinal tract.

While the *Giardia lamblia* has been described as early as 1675 by Leeuwenhoek, it is only in recent years that its significance as an etiologic factor in intestinal disease has gained prominence. One group of observers found that the incidence throughout our country was 12 per cent. The similarity of its symptomatology to other intestinal diseases calls for detailed investigation of the duodenal contents and the stools when these symptoms present themselves. Where the parasite is found, the use of atabrin, from all reports, seems to be a specific for its eradication.

THE MENTAL-HYGIENE ASPECT OF THE DEFERRED DRAFTEE

LOWELL S. SELLING, M D , Dr P H , Detroit

DURING a period of national emergency the interest of the nation is focused upon the armed forces. This is as true in time of preparation for a contingent emergency as it is during actual wartime. Behind the Army lies an extensive shadowland which cannot be ignored. This shadowland is the civilian population.

The present paper is intended to emphasize the responsibility of physicians in heightening civilian morale and in making as many youngsters valuable for our Armed Forces as possible. The physician's job should not be elimination but should be prevention, correction, and treatment.

Because of the limitation of human thinking, naval and military men who are planning to defend the country must concentrate particularly upon the selecting, training, and equipping of the military and naval forces. Their interest in the equipment may project their endeavors into industry and even into labor problems but seldom into the life problems of the nation as a whole. These matters, although they may be of the utmost importance, are left, at least in this country, entirely to hit-and-miss civilian campaigns. No agency, for instance, has as yet been established to handle problems of civilian morale, and yet it was probably the collapse of civilian morale at the end of the war of 1914 to 1918 which caused the German surrender.

When there is discontent, dissatisfaction, and antagonism among the civilian population, these attitudes are reflected on the troops. It was different before the advent of quick communication when an invading army might be a month's travel away from its homeland and so might not know of any difficulties among their families and friends until the war had actually been fought to a finish, but armies today are in touch with the civilian population, and the collapse of that population can cause the collapse of army morale. This actually occurred during the spring of 1918 in the French Army and, if the United States troops had not been available to raise population morale, it might have caused an Allied defeat.

Nature of the Problem

One of the most important groups of civilians to be considered in building up civilian morale is that group of individuals whose ages would permit them to be in the Army but who, for some reason, have not been accepted. When the whole group of 900,000 men provided for under the present draft legislation has been inducted into the Army, there will remain a large group of individuals whom we, as physicians, have certified as not being able to stand side by side with the others to take part in defending the country and to engage in the educational, recreational, and experiential activities made available by the Government to their contemporaries.

At the present time, when just a few individuals have been inducted, the majority of the male population from 21 to 36 years of age consider their deferment as a matter of good luck, but this attitude will change with the growth of the Army and a number of mental-hygiene complications will arise.

This contingency has already been strongly brought to my mind because of several cases that have been seen in the Court Clinic.

One case, particularly, reveals the fact that we are going to have a number of complications on the mental-hygiene side in dealing with deferred draftees. This case was that of a youngster 18 years of age, who, with a group of five others, went to a Navy recruiting station hoping to be taken into the Service. The other five were examined and accepted by the Navy. This boy, because of eyesight just a small degree worse than that of his colleagues, was rejected. He went into a severe depression, not so severe as to indicate that he was too unbalanced and should not have been accepted for that reason, but a reaction indicating that he felt inferior and lost—his friends were leaving him and he felt that he was not good enough to go with them. He had given up his job so that he would be able to enter the Service, and he was unemployed. He was at loose ends.

Although he did not drink, someone suggested that since he was so depressed he should have a drink. He began drinking at about three o'clock in the afternoon and at eight o'clock that night entered and drove a motor car, was arrested after hitting two parked cars,

Presented at the meeting of the New York County Medical Society, February 24, 1941.

Director of the Psychopathic Clinic of the Recorder's Court, Detroit. Series NP No. 6.

needless tests indicates a lack of skillful observation and thinking, dulls clinical acumen, penalizes the patients, wastes time and material, and gives the public an incorrect view of the cost of sound medical care.

"In the course of time, many sciences have become the assistants of medicine, so that diagnosis and treatment are established on a surer foundation. Sometimes, it has seemed, these helpers have altered the perspective and dimmed the aims of the helped by placing too much emphasis on the objective aspects of disease and too little on the subjective."

How is it possible to avoid, under any form of regimented medicine, the waste of time and material, the undue stress upon and abuse of laboratory aids, and the neglect to apply keen clinical judgment? "The engineer, the mechanic, and the artist of every sort work with materials of known composition, but you as a physician deal with a structure more complex, less understood, with a great many parts, all of which are not only self-wearing but must be self-repairing, and the

evidence for the defects of which may be quite elusive. To find the clues and to procure the incriminating evidence of damage will often tax you more than it does a detective."

Each year's crop of interns necessitates reiteration of admonitions against routinely ordering x-rays, hematologic studies, basal metabolism, and the numerous other tests that only an intern can think up on the spur of the moment for a new admission *before he has examined the patient completely*. What will happen to the *quality* and the *cost* of medical care under governmental supervision when the patient feels, to put it in the vernacular, that he is "entitled to the works"? Of more importance, what will happen when "observation, still the most informative of all clinical methods, seems so simple that it is practiced too little"? going to the oculist, but careful, tactful advice in this sphere is of value

With regard to the matter of a neurosis or mental disturbance accompanied by hypochondriasis, one could say that this is probably not the most important topic to be considered in dealing with the deferred draftee, probably 99 out of 100 boys can be told that they are not physically well enough to go in the Army without developing any untoward symptoms

We have had, however, a case brought to our attention of a boy who was told that he had heart disease. He has now become disturbed over it, believes that he is going to die, and has been going from doctor to doctor because of it. Although each doctor must admit to him, because of his intense questioning, that the heart condition does exist, it is a mild chronic rheumatic condition of which the boy would not have been aware. There is no need for medical attention other than advice at the present time, and good hygienic behavior in the future will probably take care of the matter and allow him to have as long life as anyone could expect

The Mechanisms

The fact, however, that this boy has fallen down in competition with others probably has caused the neurosis. He feels inferior, lacks security, and has to fixate on some object or some spot that will justify him in not being able to do as well as his contemporaries. He, therefore, uses the mental mechanism of hypochondriasis with cardiac symptoms to take care of this problem.

It is my opinion that lack of security and inferiority feelings will be the two primary psychologically etiologic features to be considered if we leave out those young men who were detected by the psychiatric physicians of the induction board, who are actually unstable major psychopaths or psychotic, and who cannot be assimilated in the Army.

Inferiority feelings are important in all of us. Certainly, when a boy who has a bad home background but has been able to control his inferiority feelings finds himself a failure in this critical period of his own life, he is likely to develop a reaction of inadequacy.

There have been cases brought to our attention of young men who, because of these inferiority feelings, have not been able to go back and hunt for a job until such time as they are given special advice.

These cases are infrequent, and the fact that such a major reaction occurs suggests

that perhaps they are the kind of cases best kept out of the Armed Forces.

The fact remains, however, that the civilian population is going to be full of rejected young men—left to do various tasks for the Army, for the Government, and for the administration of the nonmilitary population—who are none too stable and upon whom are superimposed these new feelings of inadequacy and inferiority.

Treatment

The physician in dealing with these problems should, first of all, make some effort to provide for correction, then the Government should make some provision so that when these difficulties are corrected the boy can be inducted in the Service. The draft physician should urge him to try a second time if it is possible. Those who cannot be corrected within a reasonable time should be sent to their physicians who must be careful not to set up such reactions as to make these people either seriously maladjusted or hypochondriacs. It must not be forgotten that each case is a law unto itself.

Our Army officials are handling the new Army in a most careful fashion, giving them warm cantonments, good food, recreation, and education to take care of our Army morale. While it is not entirely the job of the physician to care for in a tactful, intelligent way those who are behind the lines, their responsibility cannot be ignored.

When we consider the amount of damage that these unstable individuals with feelings of insecurity and inferiority could cause if they were led in the wrong direction, we must admit that it offers rather fearful problems. These are the people who—feeling the rejection by their father, the United States' Government, and in turn rejecting the father—become antisocial persons.

The implications of historical studies are that if one were to analyze the type of people who are most apt to become traitors, *saboteurs*, and spies, one would find a large number of unstable persons who could not be accepted into the Army. First of all, they must compensate for their feelings of inferiority by getting a job that gives them status, even if this status exists only in their own mind. The fact that they are doing something important overshadows the fact that they are damaging their own country to which they should be loyal. Their discontent is easily turned to account by professional agitators and, as pointed out above, they feel rejected by their

and was charged with driving while drunk. I saw him several days later and he was still depressed. He wondered what would become of him. He felt that no girls would be interested in him because he was not qualified to compete physically with those boys who had gone into the Service.

Fortunately, in his case, therapy was possible. We pointed out to him that, although he could not join the Navy because of his eyesight, his vision was not so bad that he could not get into the Army. He volunteered for the Army, was accepted, and immediately made a good adjustment.

Another case was that of an elderly man who was especially trained in engineering. Although this man's salary was twice that which he would be able to get if he were accepted in the Engineering Corps of the Army, he made arrangements for joining that branch as a Reserve Officer on active duty. Despite the fact that he had never been in the Army, he was told that he could be accepted and that he would be given the rank of Major because of his special skill and experience. The physical examination revealed that his eyesight did not meet Army standards and that there was a dubiously significant cardiac murmur, which he claims he had had since childhood and never had had any decompensation or inability to take part in active physical work. He was not accepted for the Army and, at the time I saw him, he was talking about suicide. I had known him for some time and knew that this suicidal interest was a mere passing phase, but it was obvious that the disappointment had made sharp inroads into his mental adjustment. Some family friction then developed which required psychiatric advice for correction, although his wife and he had been very congenial before the present difficulty arose. He required several months' treatment but is now reconciled to the draft situation and to his wife.

Source of the Problem

In our contacts with a local induction board, to which the Assistant Director of the Court Clinic and I have been attached as psychiatrists, we have learned of a number of cases of individuals who were rejected because they were found to be unstable and mildly psychopathic. These patients were never psychotic, neurotic, or criminalistic, and I believe are unlikely to become so. They were eliminated because they seemed unlikely to be able to get along with other people in a camp situation. In order to have the best possible ma-

terial at the present time, the elimination of such psychopaths seems desirable.

In going over the records of deferred cases I find the following phenomena that should be of interest to physicians. First of all, there is a group who were rejected for minor physical ailments—slight murmurs, dental caries, mild visual defects. In most of the latter group the visual defect is so slight that we do not consider revoking their drivers' licenses in our driver's clinic. However, these defects admittedly might keep them from being considered the best type of human material for Army service. This is particularly true when one considers that there is a risk that they would have to be given a pension without having given anything of real value to their country. They are usually rejected by the local draft board physician without any use of tact or any advice.

It must not be forgotten that the rejected draftee offers a fertile field for medical work. For the first time in the lives of many of these individuals they are being given a physical examination and are being told that there is something that needs correction. If this is properly brought to their attention and if they are given the opportunity to correct their ailment with the possibility of reconsideration by the draft board, many of these boys will not have to face the mental-hygiene problem of rejection. The problems of rejection become more acute as the rejected boy sees a large number of his friends leaving and coming back with stories to tell about camp and recounting their adventures, travels, and experiences. We can use these conditions to send the rejected boy to his physician.

Draft Hypochondriasis

The physician must consider the possibility of too much stress being laid on the physical side. Hypochondriasis can arise from improper handling of a case. It does not take much longer for a physician to give a brief explanation of what the difficulty is and to suggest that treatment can be obtained for such a deficiency than to cast this potential patient out with no help. I might point out that many more of these boys than you probably believe possible are able to pay for proper physical care, and their families are anxious to see that they get it. Several physicians in Detroit have told me that boys who have been rejected have come to them voluntarily for proper treatment. In the case of poor eyesight, when the deficiency is not great, the vanity of the boy often keeps him from

THE CLINICAL FEATURES OF ENDOMETRIOSIS

LYLE A. SUTTON, M D , F A C S , Albany, New York

IT IS the purpose of this paper to present the clinical features of endometriosis based on the study of 656 consecutive cases of this condition treated on the Gynecological Service of the Albany Hospital during the past nine years, and it represents a recorded incidence of 13.2 per cent of all abdominal gynecologic operations performed on this service during the same period. It appears most frequently in or on the various organs or structures primarily, or accidentally, situated in the pelvis of women chiefly during their active menstrual life. Regardless of its location, this tissue frequently displays the same physiologic changes as normal uterine mucosa in its response to menstruation, pregnancy, and the menopause. In fact, it is this attempt upon the part of ectopic endometrial tissue to respond to normal physiologic stimuli which produces the pathologic conditions and symptoms of endometriosis.

For purposes of discussion the various forms of endometriosis (ectopic müllerian mucosa) may be classified as follows:

1 Direct endometriosis (adenomyoma, adenomyosis interna). These lesions result from the invasion of the uterine or tubal wall by its own lining mucosa.

2 Indirect endometriosis (adenomyosis externa). In the majority of these cases the lesions are peritoneal—that is, they are not continuous with the mucosa lining the uterus or tube and form the largest and clinically most important group.

3 Extraperitoneal endometriosis (non-operative). This group is comprised of lesions found in such locations as the groin, labia, vaginal vault, perineum, umbilicus, skeletal muscles, and lung. Some may result from direct extension of a peritoneal growth, while others are undoubtedly metastatic.

4 Postoperative endometriosis. These lesions may be either intra- or extraperitoneal. They may be produced by contamination of a wound with bits of viable uterine or tubal mucosa (transplantation) or may result from a direct outgrowth of the mucosa lining the uterus or tube follow-

ing trauma such as a salpingectomy, tubal sterilization, or a wound in the uterine wall deep enough to reach the endometrium.

Owing to the limitations of this paper groups three and four have not been given specific consideration in this study.

The incidence of peritoneal endometriosis in various clinics has shown marked discrepancies and is probably due to failure on the part of the operator to recognize or record the early lesions and the scars of the extremely old ones and failure of the pathologist to find microscopic confirmation in the tissues removed. A study of laboratory material will give fairly accurate statistics regarding the number of cases of direct endometriosis (adenomyosis interna) but will give an extremely low incidence of peritoneal lesions. Peritoneal endometriosis is frequently a clinical rather than a microscopic diagnosis. Only by repeated excisions of small implants, immediate fixation, and microscopic confirmation can one learn to recognize the small early and late lesions. This procedure has been followed by Sampson¹ and his associates over a period of years and we now feel that we can usually diagnose at operation both the early lesions and the old scars. These small early and late lesions are now only occasionally removed and, therefore, many cases showing only these types of lesions may not have endometriosis on the chart as a microscopic diagnosis. While we may occasionally misdiagnose such a lesion, it is more than compensated for by those not recognized or recorded.

There is also another type of lesion which sometimes lacks microscopic confirmation. This is the clinically typical "chocolate cyst," in which the pathologist fails to find endometrial tissue in its wall, particularly the large ones with pressure atrophy of their lining. These are usually called simple hemorrhagic cysts of the ovary. This diagnosis is often made on insufficient routine sections. Immediate fixation of the entire specimen and careful selection of blocks of tissue for microscopic study by the surgeon will reveal the true nature of these cysts in a much higher percentage of cases.

While we realize that ovarian hematomas of any size which are not adherent should be viewed with suspicion regardless of the

parent-substitute—that is, the Government—and, in the same way that the neurotic rejects his hated father, they reject their hated father-substitute

It is well enough to say that the Army is not an infirmary for the treatment of neurotics and psychopaths and that the Army, therefore, should not accept these neurotics—that, of course, is a truism. Yet, it is my belief that a great deal of thought should be given by the authorities to the unstable psychopathic person who cannot get into the Armed Forces to see whether he cannot be accepted for some special branch designed to keep such a potentially dangerous person out of a civilian situation where he might cause pernicious discontent or carry out dangerous acts, or whether, perhaps, there could not be some organization to aid in their placement in industry or elsewhere where they can feel they are acceptable in the preparedness program to such an extent that they will reject any suggestions that could make them dangerous

Conclusions

I have dealt here with only one phase of one of the problems that must concern us as physicians in dealing with the civilian population, as well as problems brought to us by the military. It is my feeling that the important thing now is to secure leadership to do this work, and we, as physicians, can do our part in setting up an excellent mental-hygiene program.

One idea that seems practical comes from the persistent effort of the American Medical Association to set up a centralized agency in the Government to deal with problems of medicine. The recent formation of the Federal Security Agency has been a step in that direction, but, in view of the fact that we have heard so little about how physicians can contribute to civilian adjustment during an emergency, the creation of some highly coordinated agency to deal with these problems seems definitely to be indicated.

ENCOURAGEMENT IN THE CANCER FIGHT

Much encouragement for cancer fighters appears in the record of the past few years, says Jane Stafford, Science Service Medical Writer, in the *Quarterly Review* of the New York City Cancer Committee. A decade or so ago reports from the cancer field consisted almost exclusively of the mournful record of the rising toll of cancer deaths and of warnings to doctors and the laity alike to watch for early symptoms and to start treatment promptly. The increase in cancer deaths has, unfortunately, not yet been checked, and the oft-repeated warnings on the imperative need for early diagnosis and treatment must still be heeded.

Today, however, reports from the cancer field show constantly increasing numbers of five-year cures, constantly increasing numbers of clinic and other facilities for treating cancer, constantly increasing knowledge about the very fundamentals of cancer, constantly increasing improvements in skills and methods for diagnosing and treating cancer.

More than 36,000 five-year cures of cancer are now recorded in the archives of the American College of Surgeons in Chicago. Officers of the College believe this represents the minimum figure. Cures of cancer, especially of the skin and breast, it is explained, are now no longer such a rare experience that physicians consider them significant for reporting. The five-year cures that are reported now are far more likely to include less accessible, less easily cured cancers, which seems to make the record more encouraging.

Cancer clinics, approved by the College of Surgeons, have grown steadily in numbers. When the list of such clinics was first announced in 1932, there were 100. Six months ago the College announced it had approved a total of 345 such clinics throughout the nation. Within

another six months, the number will have increased still more, judging by past experience.

A gain of nearly 30 per cent in the number of five-year cures of cancer of the breast during the past twenty years has recently been announced by Dr. Frank E. Adair, chairman of the College of Surgeons' Committee on Cancer. Cancer of the breast, as cancer fighters well know, is more easily diagnosed and treated than some other forms of cancer because of its greater accessibility. Progress is being made, however, in treatment and cure of cancer in other parts of the body.

Surgical operations for cancer of the lower alimentary canal cure more than one-half the patients, under certain circumstances, and prospects for improvement in surgery on this part of the body for the relief of cancer and other conditions are bright, Dr. Fred W. Rankin, of Lexington, Kentucky, declared at the last meeting of the American College of Surgeons. In cases of cancer of the lowest segment of the alimentary canal, the average of reports of cures from clinics here and abroad shows 58 per cent of the patients alive and well at the end of five years, including patients with and without glandular involvement, Dr. Rankin stated. When the cancer is slightly higher in the lower gastrointestinal tract the percentage of surgical cures ranges from 61 in patients without glandular involvement to 30 in patients with glandular involvement.

Surgical removal of the cancer is the only method of treatment in these conditions which offers a favorable outcome, Dr. Rankin said. Even when the cancer is so far advanced or has spread so far to other organs that cure is hopeless, the surgeon can do much to prolong the patient's life and make it relatively pain-free and comfortable.

frequent than one would suspect and represented 14 per cent of the total number of cases

The clinical features of direct endometriosis are quite characteristic and in marked contrast to those of the more common peritoneal lesions, except in its association with myomas (45.6 per cent). Peritoneal endometriosis is often an accidental finding, but direct endometriosis of any marked degree almost invariably produces symptoms that necessitate surgical intervention.

Bleeding is by far the most common symptom of direct endometriosis. It usually starts as a menorrhagia, sometimes metorrhagia, and either may be gradually superseded by a continuous flow. The bleeding frequently reaches alarming proportions, resulting in severe degrees of secondary anemia which may necessitate transfusions prior to any operative procedure. Whether the bleeding comes directly from the tumor or is produced by some alteration in the uterine circulation is not definitely known. It is not common, however, to find any marked evidence of bleeding or accumulations of blood in the ectopic endometrial cavities of the tumor in the freshly cut specimen. Dysmenorrhea is not a constant symptom and may be due to the fact that direct endometriosis does not regularly participate in menstruation. Pain, when present, may be due to engorgement of the tumor with blood or mechanical interference with the muscular contractions of the uterus.

The palpatory findings in direct endometriosis are not characteristic. The enlargement of the uterus, if any, may be regular and closely simulate a myofibrosis, submucous myoma, or hyperplasia of the endometrium. If the enlargement is irregular, it may be due solely to the endometriosis or to its frequent association with myomas.

The diagnosis should be suspected in any woman over 35 years of age who has had several children and develops profuse uterine bleeding, particularly in the absence of any other demonstrable pelvic pathology. Curettage never cures and ordinarily fails to make the diagnosis, since only the endometrium overlying the tumor is usually recovered. This condition does not respond well to radiation and hysterectomy is the procedure of choice.

The distribution of peritoneal endometriosis is such that it suggests soiling of the peritoneum by material escaping from the fimbriated extremities of the tubes as pointed out by Sampson.¹ These situations are the cul-de-

sac and the under and lateral surfaces of the ovaries. In this series of 491 cases of peritoneal endometriosis the cul-de-sac was involved in 427 and one or both ovaries in 288. We believe that bits of endometrium set free at the time of menstruation or by other mechanical means at other times are frequently viable and when transmitted to other locations by the veins, lymphatics, or through the fallopian tubes can become implanted and grow in ectopic locations. The most frequent sources we believe are a reflux of menstrual blood through the tubes and perhaps epithelium from the lining mucosa of the tubes, particularly the fimbria. Once implanted, this tissue goes through the same cycle as its parent mucosa, is microscopically identical, and responds to the same stimuli.

Aberrant endometrial tissue situated in or on the various pelvic organs and structures produces typical pathologic lesions that can be readily recognized in gross by the operating surgeon. The appearance of the early lesions and the peritoneal reaction to the growth produce a peculiar combination of color and puckered scarring not seen in any other disease. The nearest similarity is seen in carcinomatous implants on the peritoneum, but these lack the typical coloring. The color of the small endometrial implant varies with the degree of its development and the phase of the menstrual cycle as it passes through the raspberry red to the more typical blueberry color and finally fades into a white puckered scar as all activity ceases. The peritoneum resists this subserosal growth and invasion of this tissue, and the resulting reaction gives rise to the "shotty" induration often felt in the vaginal vault on vaginal examination. The lesions on the general peritoneal surfaces rarely attain any great size, although they may be widely scattered. It is in or on the ovary that they attain their greatest size and virulence, and this organ is nearly always involved in the more extensive cases. The ovary is especially susceptible to the growth of endometrial tissue and the ultimate production of the large hematomas (chocolate cysts) which first attracted the attention of clinicians.

These cysts are prone to rupture, soil the peritoneal cavity, and further disseminate the disease. The contents of these cysts is apparently irritating and gives rise to the dense type of pelvic adhesions so characteristic of endometriosis. The rate of development of any endometrotic process is apparently quite variable. We have found quite

character of their contents, we feel that previous perforation and implantation lesions, particularly about this site, are sufficient evidence to classify these cysts as truly endometrial. Therefore, they have been included in this study. The number of cases here reported probably does not indicate the true incidence of this disease because of the failure to record early unremoved lesions and to remove tissue for microscopic diagnosis from suspicious areas at the time of operation, as the tiny lesions are frequently overlooked in the pathology laboratory. Conversely, early direct endometriosis is sometimes found in the routine microscopic examination of uteri in which the disease was not suspected. In general, direct endometriosis of sufficient degree to be of clinical significance can be recognized in gross. We have encountered several cases of early direct endometriosis with slight but definite penetration of the myometrium by its mucosa with typical muscle reaction which were not recognized in the cut specimen at the time of operation. It is difficult to state when endometrial penetration beyond normal anatomic limits has occurred and requires classification as early direct endometriosis. These cases have been carefully reviewed, and only the unquestionable cases are included in this report.

Included in this study is also a group of 28 women who had both peritoneal and direct endometriosis. This combination was not encountered in those under 31 years of age. Direct endometriosis of sufficient degree to be recognized in the gross specimen was found in association with peritoneal endometriosis on only 3 occasions, and in only 2 cases were both conditions well advanced. Incidentally, both of these patients were single and over 41 years of age. These statistics bear out the impression that we have held for a long time—that the two forms are rarely associated in the same patient. In the majority of instances the peritoneal endometriosis was an accidental finding associated with adenomyomas of the uterus and the direct endometriosis, a similar finding in the routine microscopic examination of tissue as previously mentioned.

The age incidence of peritoneal endometriosis in this study corresponds closely to that previously stated by Sampson and others. It is rare under 20 years of age or over 60. Our youngest patient was 14 years old and the oldest 61, while the average age of all cases was 35 years. In the young girl it resulted from an imperforate hymen with tremendous hematocolpos, hematometra, and bilateral hemato-

salpinx with extensive peritoneal implants resulting from the backflow of menstrual blood. In our oldest patient it was an accidental finding, consisting of old scars in a patient operated upon for carcinoma of the corpus uteri. The age incidence of direct endometriosis, often called adenomyosis interna, is considerably higher. Nearly all of the cases of peritoneal endometriosis were encountered between the ages of 20 and 50, which closely corresponds to the period of menstrual activity. The greatest number occurred between the ages of 31 and 40 regardless of the marital status. It would appear that single women between the ages of 21 and 30 show a greater relative incidence than the same age group of married women. Single women and others over 40 years who have never been pregnant also show a greater tendency to develop the disease, possibly because of the increased incidence of myomas in this group. We encountered only 3 cases of peritoneal endometriosis in colored women, in spite of the high incidence of myomas in this race. This may be explained in part by the low percentage of colored women in our locality.

Direct endometriosis occurs much more frequently in the fourth and fifth decades and almost always in women who have had children, in fact, repeated pregnancies seem to predispose to its development. This is in direct contrast to peritoneal endometriosis in which the percentage of relative and absolute sterility is high.

It would seem that certain sites have a predilection for the implantation or development of peritoneal endometriosis. The posterior cul-de-sac and particularly the uterosacral ligaments are by far the commonest sites. This is especially true of the small early isolated lesions of the type seen so frequently associated with other pelvic tumors and retroflexion of the uterus. The ovary is the next most likely site. In this series the left ovary (87 cases) was involved somewhat more frequently than the right (75 cases) and both together (126 cases) much more often than either alone. The cul-de-sac without ovarian involvement occurred in 168 cases, while ovarian lesions alone were present in only 44. This is as one might expect considering the frequent association of retroflexion of the uterus with peritoneal endometriosis and the ease with which fluids injected into a retroflexed uterus, even without pressure, reach the cul-de-sac, as demonstrated by Watkins.² Direct endometriosis of the uterus is also much more

from puberty are included in the group. The average age at onset, interval, and duration of the menses showed no greater variations than any group selected at random from our office files and, thereby, failed to show any evidence of early endocrine dyscrasia.

Pelvic pain, chiefly in the form of an increasing or acquired dysmenorrhea, is the outstanding symptom of peritoneal endometriosis. In this study 79 per cent of all the patients complained of dysmenorrhea. Of this number, 57 per cent gave it as a prominent symptom and 22 per cent as mild, while in the remaining 21 per cent it was entirely absent. Many patients cannot differentiate between abdominal pain and dysmenorrhea, and it is quite likely that the latter is even more common than these figures indicate. In some, it was present from puberty, in others, it developed relatively late in their menstrual life, but in the majority it was definitely acquired and was increasing in severity. Many of the patients have difficulty in accurately localizing their pain. It is generally referred to the back, sacrum, rectum, or lower abdomen and is usually more severe on one side than the other. Incidentally, the apparent localization of pain does not necessarily indicate the site of the maximum lesions. It may vary from mild discomfort to incapacitating pain and occur before, during, and sometimes after the menstrual flow. It is also often aggravated by walking, sitting, or riding during the period. In severe cases the tenderness and pain may persist for several days and closely simulate an attack of pelvic inflammatory disease, except for the absence of fever.

Severe dysmenorrhea may be associated with nausea, vomiting, and epigastric distress. The pain is probably due to the relatively sudden distention of the lesions with menstrual blood, stretching of the surrounding tissues, chiefly the peritoneum, and, at times, rupture of an endometrial hematoma wherever present, especially in the ovary, and release of irritating material into the peritoneal cavity. The contents of these cysts may contain viable fragments of tissue which may implant and further disseminate the disease or, by irritation of the peritoneum, provoke further adhesions. Periodic repetition of the above process gradually increases the scope and intensity of the pain. On the other hand, the pain does not necessarily have any direct relation to the amount of the disease. We have seen incapacitating pain in patients with relatively few peritoneal implantations and

complete absence in extensive cases, particularly those with chiefly ovarian lesions. This was found to be true both in cases complicated by myomas, retroflexion, and other pelvic disease, as well as those having only an extensive peritoneal endometriosis. While pelvic pain and dysmenorrhea are not pathognomonic of endometriosis, they are quite significant if the dysmenorrhea is acquired and if the pelvic pain, chiefly in the rectum and occasionally in the bladder, is confined solely to a menstrual period.

We believe that peritoneal endometriosis is not a cause of uterine bleeding. While many of our patients complained of irregular uterine bleeding, an analysis of the statistics have shown that in almost every case the bleeding was due to some other concomitant pelvic pathology, chiefly myomas or a hyperplastic endometrium.

Sterility is a common and important symptom of peritoneal endometriosis. The figures on sterility can be made to show wide variations depending on how the cases are selected and what criteria are used for their grouping. When all cases were included regardless of the age of the patient, duration of marriage, and extent of the disease, we found 38.5 per cent relatively sterile, 38.5 per cent absolutely sterile, and 23 per cent fertile. The average number of children for the whole group was 1.2. We arbitrarily considered any woman who had a child 5 years of age or younger as fertile, and, conversely, any young woman who had not had a child in five years as relatively sterile. The relatively sterile women had 1.48 children, while those considered fertile had 3.2. When we reviewed 268 cases with sufficient endometriosis to be of clinical importance as judged by their chief complaints and pelvic findings, we found 87.3 per cent absolutely or relatively sterile. Most of those classified as relatively sterile had had only 1 or 2 children, and these usually were over 10 years of age. It is obvious that statistics on sterility are not significant unless the basis on which they were compiled is stated. In contrast to this high incidence of sterility in peritoneal endometriosis, we studied 92 cases of direct endometriosis and found that 94.6 per cent of these patients had had children. The remaining 5.4 per cent were absolutely sterile. It is difficult to give figures on the relative sterility of direct endometriosis, since this disease occurs in older women and the interval since bearing their last child is thereby increased. The relative sterility in this group may also be due to the frequent

extensive lesions at subsequent operations on women known to have had no peritoneal endometriosis as late as two years preceding this operation. We have recently had the opportunity to perform a second operation upon a patient 38 years old who had peritoneal endometriosis ten years before, and we found surprisingly little change in its appearance. Neither does peritoneal endometriosis always disappear immediately following the menopause, for we have found fairly viable appearing lesions in women operated upon for some other condition at various intervals of time following the cessation of the menses. We have also seen old scars in women still menstruating regularly. It would seem that some aberrant endometrial lesions cease to menstruate prematurely, probably owing to the destruction of its functioning mucosa. It is highly probable that the rate of growth and its continuation in functioning implants are dependent upon some hormonal influence.

In a review of a large series of cases, it at once becomes apparent that the greater majority of patients who have endometriosis come seeking relief from symptoms that are not produced primarily or at all by this disease. In this series only 93 out of 491 patients had peritoneal endometriosis as an uncomplicated disease. The common association of endometriosis with uterine myomas is well known, and some change in the ovarian secretions has long been suspected in the pathogenesis of both, although its true nature has never been demonstrated. It does appear that they are in some way associated perhaps on a mechanical basis, as myomas were present in 200 of these 491 cases. Retroflexion of the uterus also seems to be a predisposing factor and was associated with 143 cases in the same series. Large simple ovarian cysts were present in 32 cases. Hyperplasia of the endometrium was also present in a large number of cases, and the significance of this finding is not definitely known and may indicate some excessive hormonal activity. Experimentally, fragments of endometrium seem to implant and grow more readily in animals treated with estrogenic substances. We have found peritoneal endometriosis in association with nearly every pelvic disease prevalent in the same age group. This common association with other pelvic pathology makes the preoperative recognition of endometriosis difficult. Apparently, many women acquire small endometrial implants on the various pelvic structures which give few or no symp-

toms and are found accidentally during operations later in life for injuries of childbirth, tumors, or other pelvic pathology.

Endometriosis does not prevent the occurrence of pelvic inflammatory disease, but the association of the two is not common except in tubal stumps. As a matter of fact, patent fallopian tubes seem to be one of the chief prerequisites for the acquisition of peritoneal endometriosis. In this study the tubes were apparently patent in over 95 per cent of the cases. There were 16 cases of chronic pelvic inflammatory disease, 13 cases of hematosalpinx, and 1 case of tuberculous salpingitis, and in all of these, as judged by the appearance of the lesions, the peritoneal endometriosis could well have been acquired prior to the closure of the tubes. Salpingitis superimposed on peritoneal endometriosis gives rise to a confusing clinical picture both before and at operation.

The symptoms of peritoneal endometriosis are due to the implantation, growth, invasion and, most important of all, the menstrual reaction of ectopic müllerian tissue wherever found. The frequent wide distribution of the lesions is such that it is impossible to enumerate all of the symptoms and signs that may accrue to this disease. In the main, the symptoms bear a direct relationship to the menstrual function and will continue as long as this phenomenon is maintained.

The onset may occur at any age during menstrual activity and is usually insidious but progressive over a period of years before these patients seek relief. In certain instances, however, the onset may be acute. We have also been impressed by the rather large number who have apparently developed the disease shortly following childbirth. In this series there are also a number of patients who have been subjected to curettage or other pelvic operation a few months to three or four years prior to the development of symptoms. While it is theoretically possible that a curettage or other pelvic manipulation might irritate the process, we do not have enough information to state that it was ever more than circumstantial evidence in any of the cases of endometriosis which we have studied. The average duration of symptoms prior to operative interference in this series was three to four years but varied from a few hours to twenty years. The average age at the onset of symptoms was 28 years or about fifteen years after the average age at onset of menstruation. This figure is undoubtedly too low, as all patients who complained of pain

uterine displacements should accompany any conservative operation to afford better drainage for the uterine cavity. In fact, any operation that preserves ovarian function should be considered conservative and, especially so, if the menstrual function and possibility of conception are also conserved. Hysterectomy with removal of one ovary and perhaps a portion of the other should be considered extensive rather than radical surgery. From the standpoint of peritoneal endometriosis, the term radical surgery should be reserved for those cases that have had complete removal of all ovarian tissue.

In this review, 84 per cent of the patients under 41 years of age had conservation of some or all ovarian tissue. In this age group only those cases with extensive involvement of both ovaries or the rectosigmoid and rectovaginal space were subjected to castration. After 41 years of age the necessity for ovarian conservation decreases and the incidence of other pelvic pathology increases so that the number of radical operations rises rapidly. Failure to castrate in the presence of extensive endometriosis of the bowel is a hazardous form of conservative surgery.

Unfortunately, the majority of the cases of peritoneal endometriosis comprise a large borderline group that requires considerable surgical judgment since no one can state where all chance of conservative surgery ends and radical surgery becomes imperative. If the patient is young and anxious to have a child, one is justified in doing a conservative operation that would be contraindicated in a woman over 40 or, perhaps, in a similar young patient who has had children and now has incapacitating dysmenorrhea. The extent and severity of the disease are also important. If the bowel is not involved, one is more justified in being conservative regardless of the extent of the lesions, especially if the patient is seeking relief from sterility or is anxious to preserve the menstrual function. The probability of a pregnancy is greater following conservative operations on peritoneal endometriosis than from the same types of operations on pelvic inflammatory disease. In our experience the necessity for secondary operations or radiation castration on any of this questionable group has been rare, which is another reason to be conservative. If a patient in the borderline group already has several children and is 40 years of age or older, it is probably better judgment to prevent further spread of the disease. Fortunately, the surgeon is often aided in

his decision by the presence of some other pelvic pathology. Uterine myomas were found in approximately 50 per cent of all our patients over 30 years of age and were frequently of sufficient size or in such a location as to make hysterectomy justifiable. As a matter of fact, our apparently high incidence of extensive and radical surgery is largely due to the accidental finding of small areas of endometriosis in patients operated upon primarily for some other condition, chiefly myomas, ovarian cysts, and injuries of childbirth. An analysis of our 491 cases of peritoneal endometriosis indicates that 153 had enough endometriosis to justify extensive or radical operation for this condition alone, although it was frequently associated with other conditions.

The development and continued growth of endometriosis depends on the presence of functioning ovarian tissue. Therefore, the successful treatment of this condition depends on careful individualization of each case and the selection of those in which it is reasonably safe and practical to conserve ovarian function or necessary to destroy it. Fortunately, a recurrence or failure to control the symptoms is not so serious in peritoneal endometriosis as in many other types of pelvic pathology, since x-ray or radium castration can always be employed later if necessary. We believe that radiation castration should not be employed prior to laparotomy because of the high incidence of errors in diagnosis and that it should be reserved for those patients who develop recurrences when small amounts of ovarian tissue are unavoidably left behind or when there is a failure of regression in unremoved endometriosis after presumably radical surgery. There were 2 patients in this series who developed a recurrence following estrogenic therapy for relief of menopausal symptoms, and they were successfully treated with deep x-ray.

Extensive peritoneal endometriosis may present technical difficulties because of its possible wide distribution, dense adhesions, and involvement of contiguous structures, chiefly the rectosigmoid and, occasionally, compression of the ureters. In order to avoid injuries it may sometimes be necessary to leave considerable amounts of endometriosis attached to these structures during otherwise successful radical operations. However, in our experience retrogression has been the rule and the need for subsequent radiation has been rare.

The postoperative morbidity in peritoneal

association with myomas The average number of children per marriage in this group was 3 2

Although dyspareunia is usually considered a possible symptom of extensive peritoneal endometriosis, particularly with involvement of the cul-de-sac, the statistics are unreliable This is especially true in attempting to gather these figures from hospital charts, as interns do not routinely obtain this information The charts will, therefore, show a marked decrease over office records

Rectal and bladder discomfort are such common symptoms in any gynecologic chart because of the frequency of hemorrhoids, cystitis, and injuries of childbirth that they are not considered of significance unless definitely associated only with a menstrual period Hematuria at that time may mean actual bladder involvement Painful defecation without bleeding or discharge and present only with a menstrual period is almost pathognomonic of endometriosis in the cul-de-sac with involvement of the rectosigmoid It is not uncommon to obtain a history of fainting or the assumption of unusual attitudes during defecation in some of these patients

The physical signs of peritoneal endometriosis which can be detected on bimanual examination are not always characteristic A typical "shotty" induration in the cul-de-sac is the most characteristic finding The large adherent endometrial hematomas of the ovary can be readily palpated and are usually tender, particularly near the menses, but cannot at times be differentiated from inflammatory disease or other pelvic tumors, benign or malignant The small lesions feel much like the adherent adnexa of inflammatory disease, while tiny lesions cannot be palpated at all The common association with an adherent, retroflexed uterus and uterine myomas combine to make the diagnosis even more difficult

The diagnosis is, therefore, made on a combination of the history and physical examination A woman over 30 with acquired dysmenorrhea, sterility if married, negative inflammatory history, and, especially if associated with a retroflexed adherent uterus, an adherent ovary and "shotty" induration in the cul-de-sac probably has peritoneal endometriosis If she has rectal and vesical pain associated only with menstruation, the diagnosis is even more certain Our resident staff listed endometriosis among the possible diagnoses in 49 per cent of the 491 cases in this study

The differential diagnosis of peritoneal endometriosis is extremely difficult because of the widespread distribution of the disease Pelvic inflammatory disease, because of its same age incidence and similar palpatory findings, is the condition most frequently confused with endometriosis Ovarian carcinomas, particularly with malignant implants in the cul-de-sac, may present identical palpatory findings Rupture of an ovarian endometrial hematoma may simulate almost any acute abdominal condition In this series there were 2 cases of acute rupture One was mistaken for a ruptured duodenal ulcer and the other for an ectopic pregnancy If the lesions are right-sided, they may be mistaken for appendicitis If an ovarian endometrial hematoma becomes infected, it may simulate a tuboovarian abscess or other infected ovarian cyst

Carcinoma of the rectosigmoid is the most important differential diagnosis, as many needless resections of the sigmoid have been performed because of failure to recognize endometriosis in this location Absence of blood and mucus in the stool, normal appearing rectal mucosa over the site of the obstruction, and at operation the typical appearance of endometriosis along with other evidence of the disease in the various pelvic structures should make the diagnosis Many extensive lesions of the sigmoid and rectovaginal septum were encountered in this review, but there were no intestinal resections or colostomies performed

The surgical treatment of peritoneal endometriosis presents many perplexing problems since it occurs chiefly during the childbearing period, and we are often confronted with the necessity of preserving this function as well as relieving the symptoms The decision on the type of operation to be performed will, therefore, be influenced by many factors such as the age of the patient, sterility, the amount of pain, extent of the disease, presence of other pelvic pathology, and in the final analysis by the desires of the patient Every effort should be made to be conservative especially in women under 40 years of age, since the condition is not, and rarely ever becomes, malignant Small areas of endometriosis on the pelvic peritoneum may be ignored, resected, or destroyed with a cautery If located on or in the ovary, relatively large portions can be easily resected Early lesions on the bowel are better left alone, for they grow slowly and rarely produce symptoms of obstruction and then only late in the disease Dilatation of the cervix and correction of

and aggravated by menstruation. Many also had excessive or irregular menstruation. A few complained of backache, swelling or bleeding from the umbilicus, bleeding from a laparotomy scar, and dyspareunia or rectal tenesmus, according to the organ or area affected. In other words, there is no pathognomonic symptom of endometriosis and, furthermore, dysmenorrhea was not a particularly prominent complaint in our patients as it was in many of Dr. Sutton's and also of Dr. Counsellor's, who wrote on this subject from the Mayo Clinic a year or two ago.

I am going to complete my brief discourse by a few remarks on the important subject of treatment as I view it. The treatment of endometriosis should be surgical excision of the lesion and, since it is frequently a disease of comparatively young women in whom ovarian conservation is desirable, the question of how much to do becomes, many times, a most perplexing problem. In the older patients in whom ablation of the ovarian function does not matter so much, roentgenotherapy or radium irradiation may be employed in addition to radical surgery, but most writers report only 2 or 3 per cent of their cases treated by these methods. We have had no experience with radiotherapy for endometriosis at the Woman's Hospital, although we recognize with others that ovarian function is essential to the growth of ectopic endometrial tissue and that cessation of the former results in regression and extensive atrophy of the growths. To conservative operative work some surgeons have added presacral nerve resection as a prophylactic against pain in the event of recurrence of the trouble, but to most surgeons it seems of dubious practical value.

As to the question of conservative versus radical surgery in these cases, I am convinced on general principles that an effort should be made to save as much ovarian tissue as possible for women in the younger age groups. Small cysts and implants on the ovary and elsewhere on the pelvic peritoneum can be excised or destroyed

with the cautery, and malpositions of the uterus can be corrected after separation of the adhesions that anchored it in the cul-de-sac. By so doing, the menstrual and sometimes even the child-bearing function of the patient can be preserved for her, and she is saved the distressing symptoms that characterize an early artificial menopause. On the other hand, more extensive lesions, particularly those that involve both ovaries, can be remedied only by more radical procedures, and a supravaginal or total hysterectomy, combined with the removal of both appendages, gives the best results. With few exceptions, if any, the ablation of the ovaries will bring about a regression and atrophy of endometriosis in the rectovaginal septum and in other places where possible injury to the bowel might be involved in removing it.

In the Woman's Hospital group the ratio of conservative to radical operation was exactly five to four, and by radical is meant the complete removal of all ovarian tissue. Of the 75 patients who underwent conservative operation, 42 left the hospital with enough of the genital tract intact to make pregnancy a possibility, while 33 were rendered sterile by hysterectomy, the removal of both tubes, or various combinations of work.

The postoperative morbidity and the immediate mortality rate are slightly greater in these cases than in a random series of gynecologic laparotomies for other conditions, such as operation for fibromyomas, ovarian cysts, or retroversion. This is due, of course, to the wide blunt and sharp dissection of dense peritoneal adhesions often required, the spill of the tarry material from the old cysts, the longer time consumed, the greater tendency to hemorrhage and shock, the disruption of integrity of the serosal or muscular layers of the bowel, and general trauma that accompanies extensive manipulation. Three of our patients died while in the postoperative stage, slightly over 2 per cent, and all of them showed signs of peritonitis with marked distention and ileus.

HELL FIRE AND TYPHOID FEVER

Among the many interesting papers of reminiscences appearing in the medical journals is one by Dr. R. H. Garthright, of Vinton, Virginia, in the *Virginia Medical Monthly*. He recalls that as late as the fall of 1898 a young doctor read a paper before the state society on "Do Bacteria Cause Disease?" and "the scholarly men of advanced age did not believe it, and in loud language declared the ideas expressed by the young doctor could not be accepted as true!" "Think of it," exclaims Dr. Garthright, "and it happened late in the nineteenth century!"

Many people then used to plug their keyholes at night, he recalls, to keep out the night air, which was considered baleful. Some towns were advanced enough to put in sewage plants, and

the question came up in Vinton. "A meeting was called, at which a bond issue for \$50,000 for putting in a sewage system was discussed. All seemed to favor the project. At the second meeting several weeks later, several citizens opposed the project. Speeches were made for and against the measure. I saw in the faces of many of the assembly, a determination to turn the matter down, and, before putting the vote, urged them to act in its favor. 'If you do not, this dangerous disease will stay with us, and kill some of you, and, knowing you as well as I do, I think I am telling the truth when I say, you will go to Hell!'" The bond issue was voted, the sewage system built, and typhoid fever disappeared.

endometriosis is somewhat greater than in other more clean-cut pelvic operations, but the mortality rate is extremely low, probably owing to the age and generally good condition of these patients. There were no deaths in our series of 491 abdominal operations for peritoneal endometriosis.

Summary

Endometriosis can be divided into four general groups as follows:

- 1 Direct endometriosis (adenomyosis interna)
- 2 Indirect or peritoneal endometriosis (adenomyosis externa)
- 3 Nonoperative extraperitoneal endometriosis
- 4 Postoperative endometriosis

Endometriosis is a common pelvic condition in women between 25 and 50 years of age and may be encountered before 20 years or after 60. Peritoneal endometriosis is frequently an accidental finding with few or no symptoms, but in advanced cases it may produce marked pelvic pathology and become an incapacitating disease.

No other nonmalignant condition presents such a possible wide distribution of lesions or more bizarre clinical features than peritoneal endometriosis.

A statistical study of 656 cases of endometriosis is herewith presented. The discussion is centered on the clinical features of 491 cases of peritoneal endometriosis and 92 cases of direct endometriosis, including their points of contrast.

The outstanding symptoms of peritoneal endometriosis are dysmenorrhea, pelvic pain, and sterility, while the chief symptoms of direct endometriosis are uterine bleeding, occasionally dysmenorrhea.

The treatment of peritoneal endometriosis should be conservative whenever possible, and particularly in women under 40 years of age. Any operation that leaves ovarian tissue *in situ* is considered conservative. Direct endometriosis of sufficient degree to produce bleeding cannot be controlled by conservative measures, and hysterectomy is the procedure of choice.

Discussion

Dr Ralph A Hurd, New York City—It gives me great pleasure to discuss Dr Sutton's inter-

esting and instructive observations on the subject of endometriosis, a lesion that has been of unusual interest to me ever since the masterful articles of Dr Sampson appeared in the nineteen twenties. I think it is particularly appropriate that Dr Sutton is doing his work in Albany, which ranks as the outstanding seat of investigation of this condition in this country.

I like the clear and simple way in which Dr Sutton has grouped endometriosis into four general varieties rather than naming the various organs in which the condition has been found. Such organs are myriad. I am in agreement with him when he states that no other nonmalignant condition presents such a wide distribution of lesions and such diversified clinical features as does endometriosis. It is also gratifying to find that the essayist strives to treat peritoneal endometriosis in a conservative way, particularly in women in the younger age groups. It may be interesting to contrast Dr Sutton's observations and conclusions on this ever interesting topic with my own that are the result of a survey made at the Woman's Hospital in New York City.

Our 361 cases are dwarfed in number by those of Dr Sutton which total 656, but I feel that we have learned a good deal from ours, nevertheless. In going over my statistics, I felt that our cases of adenomyosis interna should not be properly included in a clinical study of endometriosis, as this condition was frequently discovered only in the course of routine pathologic examination in cases where a hysterectomy had been performed for some other reason. My critical analysis, therefore, is limited to 135 cases, but in every one of these the endometriosis was the sole or a prominent contributory cause of the symptoms from which the patient sought relief.

In the course of this brief discussion I shall not go into the history of the development of this subject or cite the various theories of etiology of endometriosis, except to say that the theory of Sampson has received the widest acceptance of all and that I personally am happy to subscribe to it. The pathology of endometriosis has been well described again and again, and nothing need be said in that connection. As to age incidence, my findings are practically in agreement with those of Dr Sutton, and I also discovered the possibly significant fact that about 40 per cent of our patients had been operated upon previously, most of them having had laparotomy for one condition or another, including cesarean section, and a few having undergone vaginal plastic work or curettage. This bears out Dr Sampson's published belief that there is danger of initiating endometriosis by manipulation of the pelvic viscera at operation.

So far as symptoms are concerned, our patients complained of those for which most women with intrapelvic lesions consult a physician. One was abdominal pain, either constant or irregular

lated either to the pathogenetic mechanism of *predisposition*, which concerns the causation and distinction of the basic character of an anomaly, or to the pathoplastic mechanism of *preformation*, which concerns the preparation of the individual organism for the production of a particular psychosis. The third mechanism in the organization of any mental disorder is that of *provocation*, which refers exclusively to its instigation, activation, and actual manifestation.

Although there is no uniform biologic law governing the dynamics and integration of these coordinate morbidic elements in the individual case, it is significant that the principal effect of specific hereditary characters centers around the primary pathogenetic determination of an anomaly. Every genetic factor becomes subject to the individual environment, which exercises its provoking influence by mobilizing and modifying the phenotypical expressions of the given character. These environmental conditions naturally include the manifold biophysiologic processes that take place in the organism itself and prove to be essential to its particular life development. Therefore, it should not be concluded from the absence of a genetic anomaly in the immediate ancestors of a single patient that in such a case the disease is not hereditary, for it is not the anomaly itself which is hereditarily transmitted but only the predisposition to this anomaly—that is, the ability to develop it when the necessary peristatic conditions for the particular anomaly are present.

Biologic Definition of Normality and Adaptation

To understand the heredoconstitutional mechanism of preformation, which is especially effective in the pathoplastic differentiation of mental disorders, we must bear in mind that from the biologic point of view no clear-cut distinction exists between disease and health or between normality and abnormality. Perfect health is a condition of full biologic adaptation, while disease constitutes that state of an organism which is at the opposite extreme in its adaptive capacity. It is obvious, therefore, that normality, likewise, is merely a concept of clinical definition classifying the individual according to his capacity for self-preservation.² The normal type is best defined according to the integrity of its vital efficiency if the standards of normality are not confused with those of medic-

It is this innate faculty of *adaptation* which primarily determines the limits and qualities of a human individual with respect to his particular reactions to both predispositional and external morbid factors. The variations in these reactive abilities to protect the organism against pathologic influences depend on the degree of the individually developed physical and mental resistances that find their expression in the corresponding phenomena of constitution and character. What the character is in the province of mental development, the constitution is in the physical field. Together they form what finally defines the individual susceptibility or adaptability to morbidic elements.

These basic concepts of medical genetics explain why serious *morbid* factors, such as that for schizophrenia, although they are transmitted in accordance with the same laws as normal ones, are usually monomeric, while most of the *normal* human qualities are based on several or many hereditary predispositions. If a particular genetic factor brings about so marked a deviation from the average type of normality that the person affected by this monomeric trait becomes plainly distinguishable from other individuals, the deviation will generally involve a definite impairment of the capacity for adaptation and self-preservation, thus leading to a morbid state. On the other hand, when single hereditary factors are not potent enough to produce a distinctive condition of mental abnormality but need the cooperation of other factors for the development of a well-marked deviation, then they will usually remain without pathologic significance. They will cause mere differences in degree which are within the limits of what is ordinarily spoken of as normal.

Special Genetic Pathology of Mental Disorders

Reasonable modifications are necessary, of course, to render these general genetic principles applicable to the various types of common mental disorders, which neither exhibit any gross anatomic lesions or defects of the brain nor affect the functions of the peripheral parts of the nervous system—that is, the simple forms of psychopathy and mental deficiency, paranoic reactions, schizophrenia, manic-depressive psychosis, and senile dementia. It is to be expected that the quality, source, and intensity of the different elements, that share in the formation of such an anomaly, may vary in accordance with the actual clinical nature of the individual process. It

THE OPERATION OF GENETIC FACTORS IN THE PATHO-GENESIS OF MENTAL DISORDERS

FRANZ J. KALLMANN, M D, New York City

IN SPITE of numerous uncertainties that still exist about the intrinsic morphologic processes of heredity, it should now be clear to the medical profession that many important problems of pathogenesis will remain unsolved, or insufficiently solved, without the collaboration of genetics and the development of what may best be called a special science of *medical genetics*. There is no use in presuming that man might be an emancipated exception to any of the fundamental biologic laws. In the case of heredity it has been possible to demonstrate by a great number of clinical and experimental observations that in controlling and directing the normal or abnormal development of human beings innate forces are no less effective than the influences acting upon the organism from without.

The futility of any effort to understand the origin of complex morbid conditions without distinguishing between primary pathogenetic determinants and modifying pathoplastic agents has become particularly obvious in the field of mental disease. Medical knowledge has gained as little from the old controversy about the significance of either heredity or environment in the production of mental disorders as it has gained from any other attempt to classify intricate psychiatric problems under artificially dichotomizing or purely speculative terms. The biologic analysis of the basic mechanisms that operate in the pathogenesis of the great variety of psychotic processes and psychoneurotic reactions does not require, certainly, their pseudosystematic classification under such dichotomous headings as psychogenic and somatogenic, endogenous and exogenous, functional and organic or genetic and peristatic. Still less does it permit the relating of all deviations in mental efficiency and behavior to only one of the various functional systems that cooperate in the determination of the actions and reactions of a human organism.

The Inseparability of Heredity and Environment

The biased and oblique dispute about the

preponderance of genetic or environmental factors in the origin of mental disease can be traced to those remote times when genetics was in the same undeveloped condition as many other branches of medical science. It had little justification even in that period when heredity was interpreted as merely the transmission of simple physical or mental attributes from parents to their children.

In the meantime it has been observed that there are only a few inheritable mental characters that follow the direct mode of mendelian inheritance or are absolutely independent and insuppressible in their phenotypical expressivity. It has been found to be the rule that the relations between the various inherited predispositions to mental anomalies and the individually manifested attributes are of a much more complex nature. Even if a certain type of mental disorder is proved to be inheritable, it does not follow that heredity must be instrumental in every case exhibiting the symptomatology of this disorder or that it is always the only factor operating in its pathologic development.

General Genetic Principles

It is one of the fundamental genetic principles that any anomaly that generally results from the operation of a certain gene or a combination of genes may depend, in its phenotypical expression, upon the presence or absence of other genetic or peristatic elements and may also be able to originate from a particular arrangement of purely external factors. The limited number of possible morphologic response patterns of the human brain permits similar psychopathologic symptoms to arise from a multiplicity of biophysiologic causes, although it is equally true that practically identical causes are capable of producing a diversity of symptoms in various types of individuals whenever these persons differ in their genotypical structure, constitutional resistance, or mental responsiveness.

It is another law of modern human genetics that the genetic factors involved in the pathogenesis of mental disorders may be specific or unspecific in their phenotypical effects and are even able to act upon different components in the tridimensional structure¹ of a psychosis. These components may be re-

¹Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 8, 1940.

lated either to the pathogenetic mechanism of *predisposition*, which concerns the causation and distinction of the basic character of an anomaly, or to the pathoplastic mechanism of *preformation*, which concerns the preparation of the individual organism for the production of a particular psychosis. The third mechanism in the organization of any mental disorder is that of *provocation*, which refers exclusively to its instigation, activation, and actual manifestation.

Although there is no uniform biologic law governing the dynamics and integration of these coordinate morbidic elements in the individual case, it is significant that the principal effect of specific hereditary characters centers around the primary pathogenetic determination of an anomaly. Every genetic factor becomes subject to the individual environment, which exercises its provoking influence by mobilizing and modifying the phenotypical expressions of the given character. These environmental conditions naturally include the manifold biophysiologic processes that take place in the organism itself and prove to be essential to its particular life development. Therefore, it should not be concluded from the absence of a genetic anomaly in the immediate ancestors of a single patient that in such a case the disease is not hereditary, for it is not the anomaly itself which is hereditarily transmitted but only the predisposition to this anomaly—that is, the ability to develop it when the necessary peristatic conditions for the particular anomaly are present.

Biologic Definition of Normality and Adaptation

To understand the heredoconstitutional mechanism of preformation, which is especially effective in the pathoplastic differentiation of mental disorders, we must bear in mind that from the biologic point of view no clear-cut distinction exists between disease and health or between normality and abnormality. Perfect health is a condition of full biologic adaptation, while disease constitutes that state of an organism which is at the opposite extreme in its adaptive capacity. It is obvious, therefore, that normality, likewise, is merely a concept of clinical definition classifying the individual according to his capacity for self-preservation.² The normal type is best defined according to the integrity of its vital efficiency if the standards of normality are not confused with those of mediocrity.

It is this innate faculty of *adaptation* which primarily determines the limits and qualities of a human individual with respect to his particular reactions to both predispositional and external morbid factors. The variations in these reactive abilities to protect the organism against pathologic influences depend on the degree of the individually developed physical and mental resistances that find their expression in the corresponding phenomena of constitution and character. What the character is in the province of mental development, the constitution is in the physical field. Together they form what finally defines the individual susceptibility or adaptability to morbidic elements.

These basic concepts of medical genetics explain why serious *morbid* factors, such as that for schizophrenia, although they are transmitted in accordance with the same laws as normal ones, are usually monomeric, while most of the *normal* human qualities are based on several or many hereditary predispositions. If a particular genetic factor brings about so marked a deviation from the average type of normality that the person affected by this monomeric trait becomes plainly distinguishable from other individuals, the deviation will generally involve a definite impairment of the capacity for adaptation and self-preservation, thus leading to a morbid state. On the other hand, when single hereditary factors are not potent enough to produce a distinctive condition of mental abnormality but need the cooperation of other factors for the development of a well-marked deviation, then they will usually remain without pathologic significance. They will cause mere differences in degree which are within the limits of what is ordinarily spoken of as normal.

Special Genetic Pathology of Mental Disorders

Reasonable modifications are necessary, of course, to render these general genetic principles applicable to the various types of common mental disorders, which neither exhibit any gross anatomic lesions or defects of the brain nor affect the functions of the peripheral parts of the nervous system—that is, the simple forms of psychopathy and mental deficiency, paranoic reactions, schizophrenia, manic-depressive psychosis, and senile dementia. It is to be expected that the quality, source, and intensity of the different elements, that share in the formation of such an anomaly, may vary in accordance with the actual clinical nature of the individual process. It

holds equally true that every case may appear as another variety in the outcome and dynamics of the conspicuous interplay among the particular genetic, constitutional, and external forces involved. There can be no doubt, however, that the essential biologic effect of these disorders is always characterized by a varying degree of disintegration in vital efficiency and mental adaptation. Even if clinically the different disease groups comprise many quantitative and qualitative variations between mild and reversible reactions and drastically deteriorating processes, genetically it is not difficult to understand that they constitute well-defined entities and originate by a uniform biologic mechanism with interchangeable components.

Inheritance of Schizophrenia and Manic-Depressive Psychosis

As to the special genetic pathology of these various disease groups, which can be outlined only briefly here, it is to be concluded from a variety of family and twin studies that schizophrenia and manic-depressive psychosis are based on autosomal hereditary factors that are specific and completely independent of each other. The reported occurrence of schizophrenic psychoses in the consanguinity of manic-depressive persons must either be regarded as an accidental association of the two traits in the same families or may be explained by certain inconsistencies in the diagnostic system employed. In confining the diagnosis of manic-depressive psychosis to those cases with alternating episodes of depression and elation which do not show real hallucinations, dissociated delusions, or a definite tendency to mental deterioration, we never find that the descendants or cotwins of manic-depressive patients become schizophrenic. It is also a fact that we have not observed one single manic-depressive case among the hundreds of blood relations and twin partners of schizophrenic trait carriers who have been used by us for the study of schizophrenic families and twins.

In view of the corresponding statistical results of these surveys it is our belief that the schizophrenic genotype³ is single-recessive and tends to be modified as to the time and expressivity of its clinical manifestations by the interactions of constitutional protective forces. The predisposition to manic-depressive psychosis appears to be more penetrant, but it is probable that several genetic factors are necessary to produce this anomaly.⁴ Schizoid personalities are genetically to be

taken as belonging to the schizophrenic disease group, either as heterozygotic hybrids with intermediate expressivity or as frustrated homozygotes with inhibited latent manifestation. Similar positions in the manic-depressive group are suggested for the various types of cycloid personalities and the distinctive category of paranoid reactions.⁵

The Genetic Determination of Psychopathic Personalities

The other, or simple, forms of psychopathy do not seem to be predisposed to by specific types of morbid gene combinations. Genetically, they are classifiable as the result of minor deviations from the state of perfect adaptability to the customary environment, in the sense of secondary reactions to the failure of achieving the desirable adjustment to a given life situation. The extent and general significance of this deficient capacity for self-preservation depend on both the average biologic qualities and the common social conditions of the respective population groups. There is no such thing as absolute or unconditional adaptation of a group of like persons, since the average individual is only adapted to life in his or her particular environment.

Theoretically, the same end result manifesting itself as a psychopathic state with paranoid features can originate if a basically deficient psychopath with malicious or fanatic character equipment is distinguished by a marked lack of adaptability to the ordinary life conditions of his community or if individuals with merely slight deviations from the normal type of emotionality are exposed to an exceptionally unfavorable community situation—for instance, through the inability to talk or to hear the common language of their fellow citizens. Analogously, there is no quantitative difference between the depressive reactions that are produced either by fairly strong persons in response to a really disastrous life experience or by fundamentally unbalanced personalities responding to trivial difficulties of life.

It is again the peculiarities of hereditary equipment and constitutional strength which primarily determine the particular adaptive qualities of a psychopathic individual to his given environment. Unfavorable social situations and shattering emotional experiences in early childhood or later life are largely effective as the precipitating causes which activate certain predispositional inadequacies that would probably become manifest sooner or

later through any kind of environmental trauma. It is not the unsolved Oedipus complex, for instance, that affects the biologic development and social adaptation of an unstable personality originally or involves a genetically normal individual in seemingly insurmountable life perplexities, but it is the innate inability of a basically insufficient person to overcome the Oedipus situation and to stand up to the ordinary difficulties of an average human life. It seems appropriate, therefore, to state that the primary determinants of psychopathic personalities and reactions are constituted by those kinds of insufficiencies in the genotypical structure and characterologic development which are genetically defined as polymorphic deficiencies in the biologic organization of a normal personality.

The Genetic Determination of Mental Deficiency

Polymeria must also be assumed with respect to the genetic determination of the common types of feeble-mindedness which, like psychopathy, is far from being a clinical or biologic unit. Thus heterogeneity is the main reason why little has been definitely established as to the inheritance of mental deficiency, although there has always been much speculation and hypothesis, as Slater⁶ put it in a recent review of the field. It also explains why the rarer and special forms have been better studied on the whole than the more common forms without striking organic features.

The estimates on the proportion of non-hereditary types of feeble-mindedness vary between 15 and 25 per cent. It is claimed that about half of the severer forms of idiocy are due to cretinism and congenital syphilis. There is certainly no need here to mention that syphilis, even when acquired by the child before birth through contagion from the mother, cannot be counted as hereditary. This ought to be understood by everyone in our profession, but actually it still happens not infrequently in general discussions about heredity that the case of congenital syphilis is cited as the first and clearest instance to be admitted as inheritable.

In reference to the really inherited group of common mental deficiency, it is fair to say that the present balance of evidence is definitely for the conclusion of a multifactor type of mendelian inheritance. It is usually suggested that there are recessive, as well as dominant, genes capable of producing feeble-

-mindedness according to whether its manifestations are mild or severe. This would mean that even the circumscribed group of simple mental deficiency is not based on a single pair of specific genes but that its genotype is polymeric and may be manifested in a variety of intermediate forms.

Genetic Problems in Senile Dementia and Longevity

The urgency of thorough additional research, which is evident with regard to the genetic problems of feeble-mindedness, emerges still more clearly in the field of senile psychoses. As a matter of fact, senile dementia can at present be disposed of with the brief statement that there is still an almost complete lack of reliable information about possible predispositional or preforming factors contributing to senile mental enfeeblement. It is known only that the age at which senile dementia occurs varies as much as does the general phenomenon of longevity and that cases classified as senile psychoses are found more frequently in families tainted with some other form of psychopathology.

There are also the theories of Meggendorfer⁷ and Pearl⁸ suggesting that it is not duration of life as such which may be genetically determined but only longevity in the sense of a definite quantity of life energy and that it may be the total genotypical structure of the human organism rather than any particular gene which acts as a significant factor in the determination of length of life. The validity of these theories is supported by the observation that identical twin pairs quite frequently attain about the same great age before they die or before they develop similar senile disturbances, even if they have resided far apart and lived for decades under different life conditions. It is to be admitted, however, that no sufficient material of physiologic, genetic, and statistical data has as yet been collected to substantiate these still rather hypothetical assumptions.

Research Procedure of Medical Genetics

The most effective technic that is available for the investigation of this great variety of heredoconstitutional problems involved in the pathogenesis of common mental disorders is supplied by the *twin method* in connection with dependable descent studies. The promotion of accurate pathogenetic concepts is impossible in practically every branch of medical genetics without an arrangement of research which permits a comparison of tainted

holds equally true that every case may appear as another variety in the outcome and dynamics of the conspicuous interplay among the particular genetic, constitutional, and external forces involved. There can be no doubt, however, that the essential biologic effect of these disorders is always characterized by a varying degree of disintegration in vital efficiency and mental adaptation. Even if clinically the different disease groups comprise many quantitative and qualitative variations between mild and reversible reactions and drastically deteriorating processes, genetically it is not difficult to understand that they constitute well-defined entities and originate by a uniform biologic mechanism with interchangeable components.

Inheritance of Schizophrenia and Manic-Depressive Psychosis

As to the special genetic pathology of these various disease groups, which can be outlined only briefly here, it is to be concluded from a variety of family and twin studies that schizophrenia and manic-depressive psychosis are based on autosomal hereditary factors that are specific and completely independent of each other. The reported occurrence of schizophrenic psychoses in the consanguinity of manic-depressive persons must either be regarded as an accidental association of the two traits in the same families or may be explained by certain inconsistencies in the diagnostic system employed. In confining the diagnosis of manic-depressive psychosis to those cases with alternating episodes of depression and elation which do not show real hallucinations, dissociated delusions, or a definite tendency to mental deterioration, we never find that the descendants or cotwins of manic-depressive patients become schizophrenic. It is also a fact that we have not observed one single manic-depressive case among the hundreds of blood relations and twin partners of schizophrenic trait carriers who have been used by us for the study of schizophrenic families and twins.

In view of the corresponding statistical results of these surveys it is our belief that the schizophrenic genotype² is single-recessive and tends to be modified as to the time and expressivity of its clinical manifestations by the interactions of constitutional protective forces. The predisposition to manic-depressive psychosis appears to be more penetrant, but it is probable that several genetic factors are necessary to produce this anomaly.⁴ Schizoid personalities are genetically to be

taken as belonging to the schizophrenic disease group, either as heterozygotic hybrids with intermediate expressivity or as frustrated homozygotes with inhibited taint manifestation. Similar positions in the manic-depressive group are suggested for the various types of cycloid personalities and the distinctive category of paranoid reactions.⁵

The Genetic Determination of Psychopathic Personalities

The other, or simple, forms of psychopathy do not seem to be predisposed to by specific types of morbid gene combinations. Genetically, they are classifiable as the result of minor deviations from the state of perfect adaptability to the customary environment, in the sense of secondary reactions to the failure of achieving the desirable adjustment to a given life situation. The extent and general significance of this deficient capacity for self-preservation depend on both the average biologic qualities and the common social conditions of the respective population groups. There is no such thing as absolute or unconditional adaptation of a group of like persons, since the average individual is only adapted to life in his or her particular environment.

Theoretically, the same end result manifesting itself as a psychopathic state with paranoid features can originate if a basically deficient psychopath with malicious or fanatic character equipment is distinguished by a marked lack of adaptability to the ordinary life conditions of his community or if individuals with merely slight deviations from the normal type of emotionality are exposed to an exceptionally unfavorable community situation—for instance, through the inability to talk or to hear the common language of their fellow citizens. Analogously, there is no quantitative difference between the depressive reactions that are produced either by fairly strong persons in response to a really disastrous life experience or by fundamentally unbalanced personalities responding to trivial difficulties of life.

It is again the peculiarities of hereditary equipment and constitutional strength which primarily determine the particular adaptive qualities of a psychopathic individual to his given environment. Unfavorable social situations and shattering emotional experiences in early childhood or later life are largely effective as the precipitating causes which activate certain predispositional inadequacies that would probably become manifest sooner or

despite the great importance of mental disorders in the social order, so little attention is paid to man as an organism, who beyond a doubt transmits to his offspring genetic factors predisposing them to mental disorder. I think it may safely be said that experimental biologists dealing with the lower animals are far more careful in demanding definite controllable strains for their experiments than are the biologists who deal with the problems of medicine in the human. One may claim, of course, that such accuracy in humans is impossible, but in the hands of skilled and painstaking investigators, such as Dr Kallmann, it is really quite remarkable how much can be learned concerning the operation of genetic factors in mental disorders. One of the reasons why genetics in relation to mental disorder has not prospered is undoubtedly because many of the so-called studies of heredity in mental disorders have been carried out by the use of the armchair or desk methods as contrasted with actual field studies and personal observations on the material by properly qualified, specialized physicians. The usual procedure has been for the investigators to calculate as statisticians all sorts of relationships based on the material purporting to give accurate clinical information concerning the mental disorders under investigation. However, these statistics really mean no more than the accuracy of the original descriptions of cases and clinical diagnoses justifies, and this is one of the most important aspects of Dr Kallmann's work, which in my opinion, places it in a unique position in the field of studies dealing with the inheritance of mental disorders.

His thorough study of the genetics of schizophrenia, now known to most of us, was an example of the thorough psychiatric observational and diagnostic method and subsequent treatment of the material by proper statistical approach, with the result that it appears definite that there is undoubtedly a hereditary factor in schizophrenia. Dr Kallmann has now extended his field of observation to include studies on groups of psychotic twins where, from the nature of the material, studies of great importance will undoubtedly emerge. Dr Kallmann's investigations on twins extend at present to cover all hereditary factors in schizophrenia, manic-depressive psychosis, senile psychoses, tuberculosis, mental deficiency, and in some of the other rarer forms of neuropsychiatric disorder. His material is in my estimation unequalled, and I only hope that Dr Kallmann may have the support and opportunity to carry out to their conclusions the studies so well under way. As stated above, such a course for an able psychiatrist is usually profitless save in the sense of having contributed to the advancement of scientific medicine. It is hoped that, paralleling such a careful scientific study on the application of genetics to mental disorder, similar research units may be organized in all of the various branches of medicine to allow study by properly qualified physicians on the operation of genetic factors in all fields of medicine. It seems to me that if this is done much will be learned concerning the human organism and its potentialities upon which rational therapeutic procedures can undoubtedly be carried out.

ONE OF OUR RULERS!

According to the United Press, "The late blind senator from Minnesota, Thomas Schall, wanted so much to see that he paid the 'I Am' cult \$1,000 for a miracle." His widow testified, in the trial of ten members of this cult charged with defrauding their victims of \$3,000,000 through the mails, that her husband was promised a restoration of his sight. In order to bring this miracle to pass, the head of the cult said that "he must visualize a ray of light from the mighty I Am presence, passing through the head, moving out at right angles, passing through his eyes." Apparently this ray of light acted only through the medium of United States Treasury notes, and the inference is rather plain that the larger the denomination of the notes, the more effective they were in attracting the ray of light from the mighty I Am presence.

This story would be ludicrous if it were not

tragic, comments the *North Carolina Medical Journal*. It is hard to believe that a man with enough intelligence to acquire a seat in the United States Senate could so easily be duped by such an old racket. Albert Edward Wiggam gives as one of the marks of the educated man that he cannot be sold magic. Judging from the gullibility of Senator Schall and of many other men with academic degrees, some of our educational institutions have failed sadly in their duty to many of their matriculates.

It does not make the average citizen feel any more comfortable to think that such a man could have an important part in shaping the destiny of our country. Let us hope that the average citizen will remember this insight into the scientific judgment of the politician, when the next bill is introduced in Congress to put medical practice in the hands of the politicians.

WILL YOU SHARE YOUR HOBBY?

The Hobby Guild of America, ever active in sponsoring exhibits, is now preparing a Hobby Fair to be held at Coney Island, and is asking doctors to lend their collections. They would welcome skulls, bones, fingers, nails, teeth, or the like. The Guild rightly believes that a hobby

helps to cure "crisis nerves," and they urge that every man, woman, and child adopt one. Full insurance will cover the exhibits. The Hobby Guild is located at 34 West 33rd Street, New York City, New York. Telephone LONGacre 5-0973.

figures for normal and tainted population averages with the statistical findings obtained from the study of unselected series of monozygotic and dizygotic twins with similar and dissimilar environments

Old-fashioned pedigrees of individual families with a fascinating, but possibly accidental, accumulation of inheritable traits may indeed be nice to look at. Practically, however, they are no more useful for scientific purposes than are the casual observations of single twin pairs that may be found by pure chance to be concordant or discordant for some kind of morbid condition. Even if such a family tree is as complete as possible, especially with respect to the collateral lines of descent and the biologic qualities of the marriage partners, its results never exclude the possibility of statistical sources of error.

It is only through the investigation of average families definitely affected by an anomaly of possibly hereditary nature that we are able to determine whether there really exists a special genetic factor predisposing to the recurrence of this anomaly in the consanguinity of its trait carriers. Twin studies then serve to show how often such an inherited trait is manifested by identical genotypes, to what extent its preformation and phenotypical expressivity are modified by constitutional and environmental influences, and what varieties of clinical manifestation are, or are not, realized under these different dispositional conditions.

If an anomaly is already known to be inheritable, the ultimate purpose of a twin survey does by no means consist of demonstrating that a majority of identical twins actually develop the given anomaly together and that they do it more frequently than a comparable group of fraternal twins. What is always to be considered as clinically more important is the study of those one-egg twin pairs that differ in onset or production of a particular morbid condition. A thorough analysis of all the possible biophysiologic forces that may be responsible in a potential trait carrier for failure or success in resisting the manifestation of the latent trait might prove to be the best way of clarifying the means by which to prevent and to heal the anomaly in question.

I should not like to let this opportunity pass without expressing to the entire medical profession of the State of New York my profound appreciation of the excellent cooperation that we have received in collecting representative materials of psychotic and tuber-

culous twins. We trust that this kind of collective research will produce satisfactory results and soon rectify the old misconception that curability and inheritability are incompatible. Our main hope, however, is that it will stimulate wider professional interest in the pressing problems of modern medical genetics.

Discussion

Dr S Eugene Barrera, *New York City*—Dr Kallmann has presented a necessarily sketchy, but nevertheless timely and important, discussion of some of the problems involved in the application of genetics to mental disorders. So much is constantly being said concerning the great importance of mental hygienic and psychotherapeutic possibilities in mental disorders that it is well to present occasionally an attempt to study in some way the basic, hereditarily endowed human material on which therapeutic possibilities rest. Such a course is perhaps more painstaking, financially profitless, and thankless than some of the more spectacular approaches. Dr Kallmann himself knows this only too well, and it is perhaps due, in part at least, to such a condition that human genetics, especially in mental disorders, has lagged and perhaps been temporarily eclipsed. Then it may be that many do not like to have a disorder labeled hereditary, because they then quite erroneously develop an attitude of hopelessness and futility concerning it. But as Dr Kallmann himself has stated, a disorder for which a hereditary factor or factors may be present should not be considered as absolutely determined for its actual occurrence, and even if the disorder in its actual occurrence was hereditarily determined the situation, from the therapeutic standpoint, would not be considered differently. A proper knowledge of such a genetic predisposition would allow rather a wise and rational application of suitable hygienic and therapeutic measures in an attempt to prevent the actual occurrence of the disorder to which the individual was predisposed by heredity and to treat it, once it had developed, under proper environmental conditions.

It is an interesting but deplorable fact that,

despite the great importance of mental disorders in the social order, so little attention is paid to man as an organism who beyond a doubt transmits to his offspring genetic factors predisposing them to mental disorder. I think it may safely be said that experimental biologists dealing with the lower animals are far more careful in demanding definite controllable strains for their experiments than are the biologists who deal with the problems of medicine in the human. One may claim, of course, that such accuracy in humans is impossible, but in the hands of skilled and painstaking investigators, such as Dr. Kallmann, it is really quite remarkable how much can be learned concerning the operation of genetic factors in mental disorders. One of the reasons why genetics in relation to mental disorder has not prospered is undoubtedly because many of the so-called studies of heredity in mental disorders have been carried out by the use of the armchair or desk methods as contrasted with actual field studies and personal observations on the material by properly qualified, specialized physicians. The usual procedure has been for the investigators to calculate as statisticians all sorts of relationships based on the material reporting to give accurate clinical information concerning the mental disorders under investigation. However, these statistics really mean no more than the accuracy of the original descriptions of cases and clinical diagnoses justifies, and this is one of the most important aspects of Dr. Kallmann's work, which in my opinion, places it in a unique position in the field of studies dealing with the inheritance of mental disorders.

His thorough study of the genetics of schizophrenia now known to most of us, was an example of the thorough psychiatric observational and diagnostic method and subsequent treatment of the material by proper statistical approach with the result that it appears definite that there is undoubtedly a hereditary factor in schizophrenia. Dr. Kallmann has now extended his field of observation to include studies on groups of psychotic twins where, from the nature of the material, studies of great importance will undoubtedly emerge. Dr. Kallmann's investigations on twins extend at present to cover all hereditary factors in schizophrenia, manic depressive psychosis, senile psychoses, tuberculous, mental deficiency, and in some of the other rarer forms of neuropsychiatric disorder. His material is in my estimation unequalled, and I only hope that Dr. Kallmann may have the support and opportunity to carry out to their conclusions the studies in well under way. As stated above, such a course for an able psychiatricist is usually profitable save in the sense of having contributed to the advancement of scientific medicine. It is hoped that, paralleling such a careful scientific study on the application of genetics to mental disorder, similar research units may be organized in all of the various branches of medicine to allow study by properly qualified physicians on the operation of genetic factors in all fields of medicine. It seems to me that if this is done much will be learned concerning the human organism and the potentialities upon which rational therapeutic procedures can undoubtedly be carried out.

ONE OF OUR RULERS!

According to the United Press, "The late blind senator from Minnesota, Thomas Schull, wanted so much to see that he paid the 'I Am' cult \$1,000 for a miracle." His widow testified, in the trial of ten members of this cult charged with defrauding their victims of \$3,000,000 through the mails, that her husband was promised a restoration of his sight. In order to bring this miracle to pass, the head of the cult said that "he must visualize a ray of light from the mighty I Am presence, passing through the head, moving out at right angles, passing through his eyes." Apparently this ray of light acted only through the medium of United States Treasury notes, and the inference is rather plain that the larger the denomination of the notes, the more effective they were in attracting the ray of light from the mighty I Am presence.

This story would be ludicrous if it were not

tragic, comments the *North Carolina Medical Journal*. It is hard to believe that a man with enough intelligence to acquire a seat in the United States Senate could so easily be duped by such an old racket. Albert Edward Wiggin given as one of the names of the educated man that he cannot be sold rackets. Judging from the gullibility of Senator Schull and of many other men with academic degrees, some of our educational institutions have failed sadly in their duty to many of their matriculants.

It does not make the average citizen feel any more comfortable to think that such a man could have an important part in shaping the destiny of our country. Let us hope that the average citizen will remember this lesson into the scientific judgment of the politician, when the next bill is introduced in Congress to put medical practices in the hands of the politicians.

Case Reports

SUBLUXATION OF THE HEAD OF THE RADIUS IN INFANCY

OTHO C HUDSON, M D , F A C S , Hempstead, New York

THE occurrence of this injury is so common that more consideration should be given it in textbooks

The pediatrician is frequently called to see a small child between 18 months and 3 years of age who is crying because of pain in the arm. The history is that someone jerked the child's arm upward or that the child fell on the arm, resulting in immediate pain.

An examination of the shoulder, fingers, and wrist is normal. The extremity is held against the side with the forearm pronated. Any attempt to supinate the forearm causes pain. X-

ray examination is negative. During the examination, with one hand controlling the forearm and the opposite thumb over the head of the radius, the elbow is extended and completely supinated. Pressure over the head of the radius is made with the thumb. A distinct click can be felt as the subluxation is reduced.

A simple adhesive dressing with the arm in flexion for fourteen to twenty-one days is all the additional treatment needed.

There is no disability.

ACUTE TRAUMATIC APPENDICITIS

HAROLD LINSKY, M D , F A C S , New York City

A 28-YEAR-OLD prize fighter, H B, was admitted to the St. Albans Hospital on September 1, 1938, complaining of pain in the lower part of the abdomen. Two days before admission he had received a hard punch below the belt and had experienced a severe pain for a short time. The pain had stopped but it was followed by nausea and pain in the upper part of the abdomen. He did not vomit but his pain increased, localizing in the lower part of the abdomen. The examination showed tenderness in the entire lower part of the abdomen, with rebound tenderness and marked rigidity in the right lower quadrant.

The operation revealed no free fluid, the intestines were completely covered by dense membranous adhesions, probably due to frequent traumatizations. The cecum and the appendix, which was behind it, were plastered to the posterior parietal wall. The appendix

was elongated, thickened, and dark throughout, had a broad base, and contained several fecaliths. The appendix was removed with great difficulty, and a cigarette drain was placed into the necrotic bed.

The pathologic examination was reported by Dr. Samuel Barland as follows: "The specimen consists of an appendix measuring 7 cm. in length. The serosal surface is covered by a brown fibrinous exudate. On section the various layers are found to be necrotic. The microscopic section shows a diffuse infiltration of polymorphonuclear cells throughout all the layers. Diagnosis: Gangrenous Appendicitis."

The course in the hospital was uneventful. There was some purulent colon discharge from the lower angle of the wound that otherwise healed by primary union. The patient was discharged in twelve days with a final diagnosis of acute traumatic gangrenous appendicitis.

TREATMENT OF A SEVERE CASE OF VINCENT'S ANGINA WITH SULFANILAMIDE DERIVATIVE

LOUIS PELNER, M D , Brooklyn

SEVERE cases of Vincent's angina are fortunately rare. That these cases can be serious and often result in death is demonstrated by a report showing 8 deaths from this disease in 1938 in the state of Kansas alone.¹

Another case report shows the tremendous morbidity occasioned by a severe case of Vincent's angina involving the nose, throat, and larynx. The patient finally recovered after much treatment that included several blood transfusions.²

Personal knowledge of a severe case, treated by a colleague, in which the patient finally died because of laryngeal involvement after having received all of the accepted treatments

(including neosarsphenamine locally and intravenously, as well as irrigation with hydrogen peroxide locally) suggested the thought that perhaps another drug was necessary in these severe cases of Vincent's angina.

That neosarsphenamine intravenously and locally is not the answer to the situation in these individuals is shown by Farrell and McNichols,³ who had 6 of their patients develop Vincent's angina although they were under treatment at the time for syphilis with arsenicals. The difference between the mild cases of Vincent's stomatitis, which are easily cleared up by many forms of treatment, and the severe cases, which are refractory to treatment and often die, might

lead one to believe that there may be a secondary pathogenic invader besides the common organisms involved, perhaps because of the lowered resistance of the subject

A derivative of sulfanilamide (neoprontosil*) was used effectively in a severe case involving the pharynx, tonsils, and hard and soft palate

Case Report

S D, a man in good physical condition, aged 25, came to me with severe pain in the throat of two days' duration. There was malaise, anorexia, severe pain on swallowing or talking, fetid breath, and blood-tinged expectoration, especially on rinsing the mouth or when gargling. Physical examination revealed a widespread involvement of the oral cavity extending from the hard palate to the pharynx. There was marked redness and edema over this entire area, which made it impossible for the individual to swallow and difficult for him to talk. The white blood count revealed 8,000 white blood cells with 75 per cent polymorphonuclears and 25 per cent lymphocytes. A smear taken from the tonsillar area revealed myriads of Vincent's organisms, as well as streptococci. The temperature was normal and the pulse rate was 100.

Because of the widespread involvement of the oral cavity it was decided to try neoprontosil in full doses by mouth, along with saline irrigations every two hours. When first seen, the condition appeared to resemble an erysipelas lesion of the skin, except that it was limited to the mucous membrane of the mouth. Eighty grains of neoprontosil were given the first day, 60 grains the next, and 45 grains each day for the following two days.

Within twenty-four hours the lesion had cleared remarkably. At this time a few isolated spirochetes and fusiform bacilli were found. The streptococci were still numerous.

Coincident with the clearing of the pharynx,

* Formula: Disodium 4-sulfamido-phenyl 2-azo 7-acetyl amino 1-hydroxynaphthalene 3 6-disulfonate.

however, there appeared a mild infection of the gums, as well as a few small ulcers in the cheek. These failed to show any Vincent's organisms on smear. These manifestations cleared up markedly in one day with the continuation of neoprontosil and with the painting of neoprontosil solution (made by dissolving $\frac{1}{2}$ tablet in an ounce of water). No other medication was used. Within forty-eight hours the oral lesion entirely cleared up, the fetid odor had disappeared, and the patient was well enough to eat anything.

This case shows an extremely rapid response of a severe case of Vincent's angina following the use of a sulfanilamide compound without any other medication. Perhaps these severe, and often fatal cases of Vincent's angina are secondarily invaded by streptococci, which may be the reason why they suddenly become so severe. In that case the sulfanilamide compounds would surely be the indicated remedy. However, several smears repeated after twenty-four hours of this therapy failed to show any Vincent's organisms. This would seem to show that these compounds are even more specific against the Vincent's organisms.

Comment

A severe case of Vincent's angina was successfully treated with sulfanilamide compound (neoprontosil). In view of the extreme severity of these cases, it is hoped that a further trial will be given this drug. No other medication was given this patient, except saline irrigations, and the neoprontosil solution was applied directly to the ulcers. This local application is probably at least as effective as other aniline or acridine dyes.

A LOCULATED INGUINAL HERNIA SIMULATING UNILATERAL INGUINAL AND FEMORAL HERNIAS

WILLIAM M. UNOBSKEY, M.D., New York City

A REVIEW of the literature fails to disclose a description of a case of an inguinal hernia in which the distal portion of the sac had herniated into the femoral triangle by way of a hiatus in Poupart's ligament.

Case Report

History—A. F., a young woman aged 32, (para II), stated that for the past four years she had noticed a painless swelling in the right groin which had been progressively growing larger, the mass was partially reducible. There was no history of trauma or previous operation.

Physical examination disclosed a well-developed woman with negative findings throughout except for a swelling in the right groin, the size was about 3 cm. in width and 5 cm. in length, extending from about 3 cm. above Poupart's

ligament to about 2 cm. below. The mass was partially reducible. A diagnosis of inguinal hernia was entertained.

Operation—An incision was made parallel to, and a short distance above, Poupart's ligament. The external oblique aponeurosis, the inguinal ligament, the fascia lata of the thigh, and the femoral triangle were exposed. The external abdominal ring was also isolated, and a mass was found lying anterior to the round ligament at its exit through the ring. A mass that turned out to be a distal portion of the hernial sac was also seen in the femoral region, apparently coming through Poupart's ligament. The fossa ovalis, the usual site through which a femoral hernia enters the thigh, was visualized and was found empty. The external oblique aponeurosis was then divided parallel to the inguinal ligament. On reflecting the two flaps, the hernial sac, which was seen at the external abdominal ring lying

anterior to the round ligament, was dissected away and traced to the internal abdominal ring. The distal portion seemed continuous with the mass seen in the femoral triangle. The shelving edge of Poupart's ligament was denuded, and the femoral canal beneath Poupart's ligament was exposed. There was no mass in the femoral canal. The two sacs were continuous.

Close examination revealed that a portion of the distal end of the hernial sac of the inguinal region had passed through a hiatus in the lower portion of Poupart's ligament, about 1 inch mesial to the femoral vessels and about $\frac{1}{4}$ inch medial to the femoral ring. The portion of the sac which passed through Poupart's ligament was adherent to it. These adhesions were free, and the portion of the sac in the femoral region was pulled through the opening in Poupart's ligament into the inguinal region, thus converting two masses into one large inguinal hernia. The entire hernial sac was then dissected free from the surrounding structures and opened, the contents were replaced into the peritoneal cavity. The neck of the sac was then ligated by means of

a suture ligature, the ends of which were left long. These ends were used to transfix the neck of the sac high up under the internal oblique muscle. The gap in the inguinal ligament was closed by means of interrupted chromic catgut mattress sutures, which also took in the underlying pectineus fascia. The fossa ovalis was also closed by means of interrupted chromic catgut sutures. The femoral ring was closed by means of interrupted chromic catgut mattress sutures, also including the pectineus fascia. A typical Bassini hernioplasty was then done, closing the inguinal hernia. The external oblique fascia was closed with continuous chromic catgut and the skin with silk sutures.

Conclusion

A case is presented in which an abnormal aperture was found in Poupart's ligament. Through this hiatus the distal portion of an inguinal hernial sac had passed, forming a mass that simulated a femoral hernia.

EXFOLIATIVE DERMATITIS (RITTER'S DISEASE) TREATED WITH SULFATHIAZOLE

ADOLPH G. DE SANCTIS, M.D., and F. C. DE LORENZO, M.D., New York City

EXFOLIATIVE dermatitis occurring within the newborn period was first described by Ritter¹ in 1879. It was his impression that the disease was not contagious. Ritter's disease, as exfoliative dermatitis is commonly called, has been related to pemphigus neonatorum,^{2,3} being described by some authors as a further progression of pemphigus. This relationship is by no means settled,⁴ and discussions often arise as to the diagnosis of an exfoliating skin in a newborn, especially in the rare occurrence of several vesicles or bullae early in the Ritter's disease.

The etiology of exfoliative dermatitis in the newborn still remains obscure. A number of possible causes have been reported in the literature, but recently Kendall and Aegerter⁵ in a review of the literature and a report of a case of Ritter's disease concluded that proof was lacking in establishing any of these as etiologic agents and that the etiology of Ritter's disease was still unknown. However, infection has frequently been presented as a probable cause, and von Vonn⁶ was able to isolate *Staphylococcus pyogenes albus* or *aureus* from the tissues of his case coming to autopsy. Aegerter and Kendall,⁶ upon culturing the tissue below the exfoliating skin, found *Staph. aureus*.

Treatment of exfoliative dermatitis has been confined more or less to supportive measures. As yet we have been unable to find in the literature, any case treated with sulfathiazole.

Case Report

A white male infant of Jewish parentage, aged 16 days, was admitted with a history of having been discharged from another hospital ten days postnatal in excellent condition. Two days after he was home a small vesicle was observed above the umbilicus. This was soon followed by several vesicles about the mouth and marked exfoliation of the lower extremities. The infant became severely ill, and the exfoliation spread within the ensuing four days (Fig. 1). He had been circumcised by a Rabbi seven days after birth. Postoperative course was normal with no evidence of infection.

Physical Examination.—The baby was a full-term infant, weighing 7 pounds and 4 ounces. He was apathetic, was acutely ill, and had a rectal temperature of 100.2 F. There were several purulent vesicular and bullous lesions about the mouth and upper extremities, and two ruptured vesicles were on the right thigh. Extreme exfoliation leaving in its wake a smooth, dry and red, firm surface was found on the lower extremities, genitalia, and lower part of the abdomen, with no further evidence of vesicles or bullae than those already described. There was also peeling about the mouth. Heart, lungs, abdomen, ears, and nasopharynx were all

negative. Upon rubbing the normal or involved skin on the chest, the skin peeled easily, indicating a positive Nikolsky sign. The penis, which had been circumcised six days before, showed no other pathology than exfoliation. The sedimentation rate was 40 mm per hour. There were 3,890,000 erythrocytes, with 12.5 Gm. of hemoglobin and 11,900 white blood cells per cubic millimeter. Urine and Wassermann tests were negative. A culture of the skin showed predominating *Staph. aureus* and several *Streptococcus hemolyticus* colonies. *Staph. albus* was found on a single blood culture contaminated with other organisms.

A diagnosis of Ritter's disease was made at this time.

Sulfathiazole, 4 grains, was given immediately upon admission, and a maintenance dose of 1 grain every three hours was prescribed. The infant was placed in a heat cradle. Ascorbic acid, 25 mg twice a day, oleum of percomorphum, 2 drops twice a day, fluids by mouth, and an evaporated milk formula were also ordered.

Within two days the infant showed marked general improvement, but exfoliation progressed to include all the parts not previously involved. There were no new bullae or vesicles, the skin becoming first extremely wrinkled and then peeling, leaving behind a surface previously described. At this time he developed frequent mushy and watery stools and a temperature of 102 F rectally. The heat cradle was then removed. White blood count was 17,900 with 31 per cent neutrophils, 4 per cent eosinophils, 58 per cent lymphocytes, and 6 per cent monocytes. Eighteen per cent of the neutrophils were nonfilamented. There was one normoblast.

The temperature fell to normal on the following day, with no further rise. Feedings were taken well and improvement continued. The Nikolsky sign was found negative four days after admission, and exfoliation had diminished considerably. Two days later the skin was clear, with minimal evidence of peeling. Stools became normal within five days following the onset of diarrhea. Sulfathiazole was discontinued four days after its first administration. The infant was discharged ten days after admission in the excellent condition he had maintained for four days. He had gained 10 ounces while in the hospital.

Discussion

The question was raised early in this case whether this was one of exfoliative dermatitis or one of pemphigus neonatorum. However, after several days of observation and upon seeing the extreme exfoliation with no further bullous or vesicular formation, the general opinion was in favor of Ritter's disease as the diagnosis.

It was felt that the rise in temperature was due to the heat tent. The diarrhea was probably a complication of sulfathiazole since immediate improvement in the stools was observed upon discontinuing the drug.

Fig 1

Because no specific therapeutic measures were known and because of the possibility that the etiology of Rutter's disease might be *Staph aureus* or *albus*, sulfathiazole was administered in this case. Opinion was unanimous that the infant made remarkable progress under a sulfathiazole regimen.

No relationship could be definitely established between the disease and the circumcision.

Conclusion

We suggest the use of sulfathiazole in the

treatment of pemphigus neonatorum or exfoliative dermatitis in the newborn.

"A DOCTOR IS A FUNNY GUY"

During the influenza epidemic, when nearly everybody except the doctors were sick, someone asked what happens when the doctor gets sick, says the *Journal of the Medical Association of Alabama*. This is the question. "If a doctor is doctoring a doctor, does the doctor doing the doctoring have to doctor the doctor the way the doctor being doctored wants to be doctored, or does the doctor doctoring the doctor doctor the doctor in his own way?"

A Miss Clara May Waldron seems to have answered the question with a poem entitled "A Doctor Is a Funny Guy."

A doctor is a funny guy!
He tells us that we're sure to die,
If we don't hustle into bed
The minute that our throats get red,
And temperatures rise two degrees,
And we begin to cough and wheeze.
But when he gets the self same way,
He thinks he's made of tougher clay,
That he can gambol in the rain
In spite of fever, cough, and pain
His rules, when other folks are ill,
Applied to him, are simply nil
He's different, tho he can't tell why
A doctor is a funny guy

YOUR COMMITTEE APPOINTMENT

The committees cover every phase of economic and scientific endeavor in which medical men can be interested, and to be appointed to a committee should be, and can rightly be, considered an honor. But such honor is of no value unless a man feels the necessity of lending not only his support but his presence at committee meetings. The association needs every man's constructive view in committee deliberations, especially in these momentous times. Once a man gets into the swing of medical thought he will miss the enthusiasm of committee contacts if unable to attend.

An exchange of ideas in local societies will soon wear away the barrier of indifference and each individual, as well as the society as a whole, will be the gainer, but each one should attend his committee appointments without fail. Democracies are controlled by the associational ideas that are freely given in committee or other similar bodies deliberating for the good of the whole. There is something of interest happening which you lose by not attending. Your committee chairman and the officers need your help as well as criticism. Dictators or inside cliques will find no place in any association where well-functioning committees are found.—B J Branton, M.D., president, Minnesota State Medical Association.

CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the August 1 issue and will concern "The Use of Human Convalescent Serum."

The Use of Vitamin B Fractions

DR EUGENE F. DUBOIS. The conference today deals with the use of the vitamin B fractions. We are fortunate in having with us Dr. Norman Jolliffe of the New York University College of Medicine.

DR NORMAN JOLLIFFE. Since the clinical investigator has had available several of the crystalline B vitamins in amounts adequate for clinical study, many advancements have been made in the field of nutrition. These advancements have resulted because it is now possible to give these pure chemical substances singly and in large doses, both of which were impossible when the B vitamins were available only in concentrates.

One of the advancements resulting from the controlled use of these synthetic vitamins is the ability to recognize, to some extent, the specific clinical manifestations of deficiency of certain of these specific vitamins. For example, when brewer's yeast was the only available source of the B vitamins, we were unable to tell which of the fractions produced the improvement. For instance, we recognized the syndrome, now known as ariboflavinosis, as a deficiency of some fraction of the B complex. This syndrome consists of cheilitis and fissures at the angles of the mouth and, in more advanced cases, filiform excrescences in the nasolabial folds and sometimes over the cheeks and the forehead. We knew that by maintaining a patient with a diet poor in the entire B complex those signs did not, as a rule, improve and often grew worse. When we supplemented this diet with whole liver, liver extracts, brewer's yeast, or autolyzed brewer's yeast, these signs disappeared, but we were unable to say which of the fractions in the B complex brought about this improvement. It was not until riboflavin became available that we were able to show that these signs were manifestations of riboflavin deficiency.

In the same way the etiology of several

other manifestations of pellagra was proved. Nicotinic acid therapy is followed by clearing of the scarlet-red stomatitis, the diarrhea, and the characteristic dermatitis, but it is not followed by a cure of the peripheral neuropathy. Thiamin chloride, however, will relieve the peripheral neuropathy in pellagra.

In addition to allowing us to recognize the specific clinical manifestation of a deficiency in a specific B vitamin, the true etiology of certain syndromes that were not heretofore suspected of being a deficiency disease has now been demonstrated. For example, a neurasthenic syndrome has recently been shown, I believe, fairly conclusively by Williams, Mason, Wilder, and Smith to be a manifestation of thiamin deficiency. They placed a group of women at rest on a diet deficient in thiamin and apparently adequate in everything else. The resulting symptoms were those of a neurasthenic syndrome. By the addition of thiamin to the diet, these neurasthenic symptoms disappeared. Similarly, workers in the South have shown that many of the so-called neurotic manifestations of pellagra, either preceding or accompanying the clinical signs of pellagra, were relieved by nicotinic acid.

A third advancement resulting from the availability of the crystalline vitamins is the proof that deficiency disease in man is usually a multiple deficiency. This is too well known to require amplification. Pellagra is the classic example.

There are two important principles I wish to stress in the therapeutic use of crystalline vitamins.

First, err on the side of giving an excess rather than giving too little. I know of no experiment on human beings which has been set up directly to prove this point. However, we do have experiments that I think fairly well indicate this point. In groups of patients

having a "standard" polyneuritis, those receiving the predicted maintenance dose of vitamin B₁ showed no improvement within one month. Those receiving twice their predicted maintenance requirement showed minimal improvement. Those receiving four times this requirement showed much better improvement, while those receiving four times their predicted maintenance requirement plus 10 mg of thiamin daily by parenteral injection showed still better improvement. So we believe that the rate and degree of improvement in these "standard" patients is directly related to the amount of thiamin, that we must give at least two times the predicted daily requirement to get any response at all, and that the best response is obtained when we give somewhere between four and twenty times the maintenance dose. We have carried these experiments further and have given forty, fifty, sixty, and one hundred times the predicted maintenance requirement without significantly better results. We cannot say whether five times or ten times the predicted requirement would have given as good results as twenty times.

The second important therapeutic principle I want to emphasize is this. There is something in a good diet that you cannot supply by any combination of the crystalline vitamins now available or supply by any of the concentrates. I think I can show you that. We placed these "standard" patients on the "basal" diet supplemented by 10 mg of thiamin. The response, as a group, in ten days showed 40 and 60 per cent motor and sensory improvement, respectively. Other groups were given—in addition to the basal diet plus 10 mg of thiamin—nicotinic acid, ascorbic acid, or riboflavin, either singly or in combination, with the same results. The addition of the vitamin B complex by mouth, or parenterally, also did not better the results.

DR H B RICHARDSON: Certain parts of the B complex?

DR JOLLIFFE: No, the entire B complex, either given by mouth or parenterally. By the entire complex I mean brewer's yeast or liver. These did not increase the rate of recovery. However, the "standard" patients who received a good diet plus 10 mg of thiamin, almost all showed further improvement within ten days. This means that there is something in a good diet which we cannot supply by giving yeast or liver extracts, we cannot supply it by any of the crystalline vitamins studied or by any combination of these vitamins studied. So now I think that

we have illustrated two important therapeutic principles. First, err on the side of giving an excess rather than too little of the crystalline vitamins, second, in treating patients with any deficiency disease, in addition to administering the specific vitamins, treat the patient with a good diet.

I will relate a case history illustrating this point. A 34-year-old, white, female patient was transferred to our service from an institution for the care of epileptic cases, where she had been a patient for five years. On admission she had scurvy, riboflavin deficiency, and pellagra. We placed her on our "basal" diet. First, we gave her ascorbic acid and the scorbutic manifestations promptly cleared. We then gave her nicotinic acid and the scarlet-red stomatitis cleared within forty-eight hours, and in about a week the dermatitis began to show definite improvement. We then gave her riboflavin and cleared up the cheilitis and angular fissuring. In the meantime, because of the basal diet, she developed a polyneuritis. We then gave her thiamin and cleared up the polyneuritis. The specific signs of all of these deficiency diseases cleared following the use of the crystalline vitamins, but the patient had not gained strength or weight and was still a thin, pitiable-looking sight. She did not have the sore mouth, the cheilitis, the dermatitis, or the polyneuritis, but she was still a sick person. Then we gave her a good diet and within a period of a month she gained 20 pounds and regained her strength. In other words, treatment with these pure chemical substances is not adequate treatment for the patient. You are only treating the specific manifestations of a specific clinical deficiency.

DR OSCAR BODANSKY: What do you define as a good diet? What is the proportion of the various constituents?

DR JOLLIFFE: Our "good" diet is made up of large amounts of meat, including liver or pork, fresh vegetables of all kinds, 16 ounces of orange juice, whole wheat bread, whole grain cereals, butter, milk, cream, and eggs. There is not a single refined article of food, except for a minimum amount of sugar, in the diet. It gives about 1,000 international units of thiamin, and it is rich in all of the other essential elements of nutrition. Our basal diet is inadequate, at least in thiamin, riboflavin, and nicotinic acid, because we have seen polyneuritis, riboflavin deficiency, and pellagra develop in persons consuming this diet and then be relieved by thiamin, riboflavin, and nicotinic acid.

DR EPHRAIM SHORR You include 16 ounces of orange juice Now, would it not, for economic reasons, be possible to substitute for the 16 ounces of orange juice ascorbic acid and still have that diet in all other respects optimum?

DR JOLLIFFE I would think, as far as the development of scurvy is concerned, yes, but orange juice contains factors other than vitamin C

DR SHORR Sixteen ounces is a rather high quota in any diet

DR JOLLIFFE That is so, but these diets are not for maintenance but for therapy

DR DuBOIS What are the main constituents of the basic diet?

DR JOLLIFFE The main constituents are rice, white bread, long-cooked vegetables, butter, and lard

DR JANET TRAVELL May I ask a question about the maintenance of these patients? For curative purposes you gave large doses of crystalline vitamins plus a good diet When you have cured the patient, do you continue the maintenance doses of vitamins or is an adequate diet sufficient? Have they some special need for these vitamins?

DR JOLLIFFE Frankly, most of the patients go out and return to the diet they were on before, however, they are given dietary instructions that include taking daily a source of the entire B complex, such as brewer's yeast

DR TRAVELL What do you consider to be the "predicted daily requirement" of the members of the B complex which you mentioned?

DR JOLLIFFE These vary with age, weight, caloric intake, and activity But for a man weighing approximately 70 Kg doing light or sedentary work and consuming approximately 3,000 calories, I would consider any diet containing less than 2 mg of thiamin, 3 mg of riboflavin, and 20 mg of nicotinic acid as requiring upward revision I think an optimal diet should contain even more, possibly 3 mg of thiamin, 5 mg of riboflavin, and 30 mg or more of nicotinic acid I know of no data concerning the known requirements of pyridoxine or pantothenic acid

DR DuBOIS We are trying to revise our hospital diet so that it will be less expensive and yet contain an adequate supply of vitamins The question comes up whether it is safe to use concentrates of the vitamins. It is quite evident from what has been said that we have to keep up a basic diet that is of high quality

DR Bodansky, will you continue the discussion from the chemical standpoint?

DR BODANSKY I should like, first, to elaborate the point which Dr Jolliffe raised—namely, that crystalline thiamin is not as effective in treating thiamin deficiency as a "good diet" containing the same amount of vitamin It seems to me this finding indicates one or more of several interesting possibilities There may be another factor in the "good diet" which is also capable, to some degree, of preventing what we designate clinically as thiamin deficiency Or there may be some factor present in the "good diet" which enhances the effectiveness of thiamin Finally, we must consider the possibility that certain conditions of a physicochemical nature may influence the efficiency of thiamin It is of interest in this last connection to note that irradiated ergosterol in a dispersed state, as in milk, is more effective in the prevention of rickets than the same amount of material in a concentrated form.

There is good evidence for the existence of factors in the vitamin B complex besides those that have already been defined as chemical compounds and that have been mentioned by Dr Jolliffe One of these is vitamin H, or the anti-egg white injury factor Though the chemical structure of this vitamin has not yet been determined, it has been demonstrated with a high degree of probability that it is identical with biotin and coenzyme R Another factor in the vitamin B complex which has received a good deal of attention recently is the factor that prevents graying of hair (achromotrichia) It has just been reported that para-aminobenzoic acid exerts a considerable anti-gray hair effect It should, of course, be mentioned here that the effects of vitamin H and the anti-gray hair factor have so far been observed only in animals

In regard to the point that more than one substance may participate in the prevention of an observed deficiency, it has been shown that pantothenic acid also plays a role in the prevention of achromotrichia, although it alone is not completely effective. Again, it has been found that optimal growth in rats is not obtained even when all the known factors of the vitamin B complex are added to a diet adequate in other vitamins There appears to be still another as yet unidentified necessary factor obtainable only through the addition of liver or rice-bran concentrate

A recent finding indicates that the factor of balance of the vitamin B components in the diet may be of importance Choline has also

been considered as a member of the vitamin B complex, deficiency of this member in the diet leads, in rats, to fat infiltration of the liver Gyorgy and Goldblatt have shown that the addition of pyridoxine (B_6) aggravates the specific effects of the choline deficiency It must be emphasized that this finding is so far of theoretic interest and has, as yet, no therapeutic applicability

Consideration of the marked derangements that result in the various vitamin B deficiencies leads us to think of how the various factors in the complex may be involved in the normal functioning of the cell We have a little information here that is of great interest As you know, the activities of body cells depend upon energy changes, the most important changes of energy are associated with oxidation-reduction reactions The cells contain pairs of substances which constitute reversible oxidation-reduction systems and which form series through which atoms are transferred from the foodstuff molecule at one end of the series to molecular oxygen at the other end During the past few years it has been discovered that some of these substances in the oxidation-reduction systems are members of the vitamin B complex For example, the yellow enzyme that Warburg and Christian found to participate in the oxidation of hexoses turned out to be a combination of riboflavin phosphate and a protein The various coenzymes involved in similar oxidations were found to be phosphopyridine nucleotides, in which the structure of nicotinic acid figures prominently The oxidation of carbohydrates also involves the action of the enzyme, carboxylase It has been shown that the associated coenzyme that used to be called co-carboxylase is thiamin diphosphate Thus, we can see that certain members of the vitamin B complex are fundamentally involved in cellular processes and indeed merit the name "vitazymes," which has been given to them Future work may reveal similar roles for the other members of the complex

DR DuBois DR Dunning, have you any comments from the standpoint of the results obtained here in the Neurological Department?

DR HENRY S DUNNING During the last year and a half I have examined several patients in the New York Hospital with polyneuritis, variously classified as infectious, toxic, allergic, due to nutritional deficiency associated with alcohol, and idiopathic Therapeutically, they all had bed rest and received a normal diet and, with the exception of the allergic case, the whole vitamin B

complex in the form of wheat germ or yeast and, in some instances, additional thiamin chloride and B_6 by injection The results have varied widely, and the conditions were such that we cannot determine the effect of any one of the vitamin B fractions, nor can it be said with surety that the use of vitamin B in any form has caused the recovery of any patient However, on the basis of the ease with which myelin degeneration can be produced in the nerves of chickens fed on polished rice, it would seem advisable to give the whole vitamin B complex in addition to a normal diet to patients in whom neurones have been injured

DR DuBois Have you gone as high in the dose as Dr Jolliffe has indicated?

DR DUNNING I think the highest dose we have ever given of thiamin chloride was 100 mg per day It happened to be in a patient who made a complete recovery

DR DuBois These were patients rather more severely deficient I gather than Dr Jolliffe's standard type?

DR DUNNING Definitely more severe, they required hospitalization

DR DuBois What has been your observation, Dr Jolliffe?

DR JOLLIFFE We do not feel that we can test the therapeutic response in polyneuropathies other than in the "standard" group—that is, in patients with a mild polyneuritis—for the simple reason that those with more advanced polyneuritis may have relatively irreversible anatomic changes We have taken, for demonstration, patients that no one thought would ever make a satisfactory recovery—patients with bilateral foot drop and paresis of two or more extremities Treatment with a good diet plus vitamin B complex and large amounts of thiamin, usually 20 mg but often as high as 50 mg twice a day, usually leads to improvement sufficient for economic rehabilitation This type of evidence only suggests that thiamin is of value, though I feel it definitely is Patients with this degree of involvement are so infrequent that we cannot get groups of comparative severity with which to compare one with the other We only have the clinical impressions that large doses of thiamin and B complex, in addition to a good diet, are of value in these advanced cases

DR RICHARDSON Do you have any laboratory aid in diagnosis?

DR JOLLIFFE We run thiamin and co-carboxylase blood determinations We also use the pyruvic acid tolerance curve All are

still experimental and interpretation is difficult

Summary

DR. HARRY GOLD The complex subject of the uses of the vitamin B fractions has been greatly simplified by the discussion in the conference this morning. Our knowledge of clinical B deficiencies has advanced rapidly since the discovery of the pure principles of the B complex. One may now recognize fairly pure nicotinic acid, riboflavin, and thiamin deficiency, although all three deficiencies may exist in one and the same individual. The chief symptoms of ariboflavinosis are cheilitis, fissures at the angles of the mouth and dermatitis of the nasolabial folds, of nicotinic acid deficiency, stomatitis, diarrhea, dermatitis, and certain neurotic manifestations, and of thiamin deficiency, peripheral neuropathies and a neurasthenic syndrome. There are as yet no laboratory guides to the diagnosis of B deficiencies which are sufficiently satisfactory for general use. Two principles regarding the use of vitamins were emphasized: (1) to err on the side of giving larger doses rather than smaller ones, especially in the treatment of deficiency diseases, (2) to use a good diet,

since it contains factors, as yet unknown, which are effective in controlling deficiency diseases and which cannot be supplied by either B concentrates or by combinations of the pure vitamins. An interesting example was cited of a patient who suffered with a nutritional defect in whom all the specific manifestations of the known B factors were abolished, but the patient remained in a state of ill health. She recovered rapidly only after an abundant mixed diet was supplied. A good diet is one that contains meat, including liver and pork, fresh vegetables, orange juice, whole wheat bread, whole grain cereals, butter, milk, cream, and eggs. It should contain not less than 2 mg of thiamin, 3 mg of riboflavin, and 20 mg of nicotinic acid, and preferably somewhat higher amounts of all of these.

After a patient has been cured of a vitamin B deficiency disease by means of the pure vitamins, his state of improved health is maintained by a good diet and daily amounts of B complex in some such form as brewer's yeast. Interesting considerations regarding factors that have not yet been identified, the interaction of vitamins, and their mode of action were discussed.

CLASSES IN HEALTH AND HYGIENE

Classes in health and hygiene for men were recently held at the Fifth Avenue High School, Pittsburgh, on six Monday evenings. The classes began on March 24. They were held from 7 to 8 o'clock, sponsored by the Allegheny County Medical Society in conjunction with the Pittsburgh public schools. The speakers were members of the society, furnished through its Bureau of Medical Information.

The men eligible to attend were those employed in service merchandising, retail or wholesale, hotels, restaurants, and amusements.

In these six talks the subjects were those of interest and importance to the layman. He was given authoritative medical information on the aspects of health and disease uppermost in his mind.

AS SPOKEN

"American students are not so numerous in England now. A few remain, however, and make their contribution to life in the blitzkrieg. Quant phraseology and self-confidence are as characteristic of the New World as the Englishman's Norfolk jacket and protruding teeth are symbolic of the Old. In a tutorial class in pharmacology the other day, I asked an American to distinguish between a vermicide and a vermifuge. The definition of a vermicide offered no difficulty, but he faltered over vermifuge. Finally, mobilizing all his histrionic resources while his colleagues listened with growing amusement, he said emphatically: 'Well, when the worm spots the anthelmintic coming through the pylorus, I guess it just beats it to the rectum.'"
—Picked from the Lancet by the J.A.M.A.

Attention

Those who asked for reprints or other information as to the scientific exhibit on brucellosis are asked to communicate with Lieutenant Commander Harold J. Harris at the Brooklyn Naval Hospital, Brooklyn, New York, or at Westport, New York, by mail. Dr. Harris had a notebook in which the names of all those who made such requests were written, but in the dismantling of the exhibit the notebook was lost.

Index of Minutes of House of Delegates—1941

The minutes of the Monday evening and Tuesday sessions are included in this issue (Sections 64-88). The minutes of the Monday morning and afternoon sessions appeared in the June 15 issue (Sections 1-63)

HOUSE OF DELEGATES MINUTES OF THE ANNUAL MEETING

[Continued from page 1304 of June 15 issue]

April 28 and 29, 1941

Evening Session

Monday, April 28, 1941

The session reconvened at eight o'clock.

SPEAKER BAUER The House will be in order

Is there a quorum present, Mr Secretary?

SECRETARY IRVING There is

The Chair recognizes Dr Van Kleeck, Chairman of the Reference Committee on Report of the Council, Part VI, Medical Relief

64 Report of the Reference Committee on the Report of the Council—Part VI—Medical Relief (Section 81)

DR. LOUIS A. VAN KLEECK, *Nassau* The special subcommittee has accomplished what we have strived for years to effect. The plan, which the committee has adopted and the State Department of Social Welfare and the Council have approved, should receive the endorsement and approval of the House of Delegates, and the success of its operation depends upon the co-operation of every member of this Society.

To understand fully the importance of the plan, the reference committee wishes to call your attention to the Report of the Council in 1939 on Medical Relief. The Committee on Public Relations and Economics recommended at that time

- 1 Decentralization of welfare care,
- 2 Local professional advisory committees and/or local medical director, and
- 3 A fee schedule

After a meeting of welfare officers called by the Commissioner of Welfare on November 26, 1938, the Social Welfare Department advised the committee that the local welfare officers were not in favor of adopting the proposals of this Society.

The Reference Committee in 1940 reporting on Part II of the Council's Report on Medical Relief recommended to the House of Delegates that a special subcommittee of the Committee on Public Relations be established. This recommendation was carried out, and the following committee was formed:

E Christopher Wood, M.D., *Chairman*

Carleton E. Wertz, M.D.

F Leslie Sullivan, M.D.

Your reference committee is not disposed to alter or make recommendations which might in any way change the purpose or accomplishments of the plan submitted in the report. We do, however, wish to bring out certain points of the plan for thorough understanding and emphasis.

I quote now from the Joint Statement from the New York State Department of Social Welfare and the Medical Society of the State of New York:

" 'Principles and Discussion' represents the position taken by the State Department of

Social Welfare (under the Public Welfare Law) in regard to the various medical welfare policies adopted by the House of Delegates of the Medical Society of the State of New York during the past several years. Also included is an outline of Basic Principles of a New Medical Plan, approved by the State Department of Social Welfare, which is now being put into effect by the State Department in various localities. This is the Medical Plan referred to in the discussion below.

"Under the Public Welfare Law, local welfare officials are empowered to provide medical care on a salary basis or on a fee-for-service basis, consequently the indigent patient may not have or may have the right of free choice of physician according to the procedure adopted in any given locality. In addition, if they are to receive reimbursement from the state, their local welfare departments must be operated under the Rules and Regulations promulgated by the State Department of Social Welfare.

Any platform adopted by the State Medical Society, or by local medical groups, has no force whatever in effecting the conduct of medical relief work unless agreement can be reached with the state and local departments of welfare concerning this platform. Such agreements, if reached, are essentially mutual understandings and in no sense abrogate any portion of the Public Welfare Law. It should be noted further that the local welfare official is legally responsible, to his community and to the state, for the entire conduct of his department and he can neither delegate nor share this responsibility. He can seek and accept advice or suggestions concerning medical problems and procedures, but in the final analysis responsibility for all decisions rests solely on him.

"The State Department of Social Welfare agrees that there are advantages in the establishment of a medical advisory committee in each public welfare district and agrees to advocate the use of these committees and to assist in a general determination of their functions. Under the Public Welfare Law, these committees can advise and suggest, and can recommend policies for supervision and administration, but the responsibility for all acts and decisions must remain—and we feel should remain—in the hands of the local welfare official. State reimbursement on a local fee schedule is conditioned upon the State Department's approval of this schedule as being reasonable for the particular community rather than on the basis of a statewide fee schedule. Abolition of the system wherein medical questions are submitted to the State Department for decision is brought about automatically through the introduction of the new medical plan and the 'prior authorization' system is transferred to the local agency under local professional control.

"The attention of the local public welfare officials is called to the value of securing the full cooperation of his county medical society in the development of an approved local medical program and in the selection of a competent physician to act as Medical Director or Medical Consultant on his staff. The State Department recommends that he request the medical society covering his public welfare district to submit a list of physicians recommended by the society as suitable for such appointment and meeting the requirements established by the State Board of Social Welfare, or request the medical society to comment upon the qualifications and professional standing of a licensed physician selected by him as a candidate for appointment as Medical Director or Medical Consultant. Attention is called to the value of an active professional advisory committee in providing the local public welfare official with professional advice in the development and revision of the policies included in the approved local medical program, in the arbitration and discipline of professional problems and the operation of survey boards to review and plan proper medical care for persons suffering from prolonged or disabling illnesses or presenting special or unusual medical needs. The medical advisory committee should be appointed from a list nominated for the purpose by the county medical society.

"In conclusion, it should again be emphasized that under the law, the welfare patient is not guaranteed the right to choose his own physician, and the physician is not guaranteed the right to treat his own patient with a commitment of payment for his services. But, if the physicians of a given locality can agree among themselves to formulate and to participate seriously in a plan adapted to the medical needs and medical and economic resources of their community, the Public Welfare Law and the regulations of the State Department of Social Welfare make it possible for the indigent patient to choose his own physician and the physician to treat his own patients with payment for his services supplied from public funds. Although the local public welfare official is responsible for providing necessary medical care for indigent persons, the determination as to the medical needs is now by law 'made with the advice of a physician'."

To quote again from the report, headed "Local Medical Care Plan—Basic Principles"

"Recognition by public officials, physicians, hospital administrators, and all other professional personnel, of the Public Welfare Commissioner's legal responsibility and authority, within existing appropriations, to provide medical care for all persons, under its care, and for such persons otherwise able to maintain themselves, who are unable to secure necessary medical care."

This has been the law, but is inoperative.

"The establishment of a central unit, with administrative responsibility for the authorization and issuance of medical care, and directed by a full-time or part-time physician, who, in the discretion of public welfare official,

may be supported by a Medical Advisory Committee, follows recognition of the fact that sound medical program administration requires

- (a) Professional medical judgment and controls such as can be given only by a physician
- (b) Simplified and smoothly operating procedures to effect the referral of patients to physicians for treatment
- (c) A clearly defined plan for keeping the social service staff informed of health, medical, and medical social treatment needs of their clients
- (d) An accounting system

"Whenever feasible, the same plan for providing medical care shall be used for all categories of public assistance in order to obviate confusion to the recipient and medical attendant, and to aid in the simplification of administrative and accounting procedures."

Now, to quote from the Principles and Discussion, the first subdivision thereof, "The Medical Aspects of Medical Relief Should Be Supervised by the Medical Profession"

"It was agreed, however, that an 'advisory medical committee' should be established in each public welfare district and that this committee should act in an advisory capacity only. It was agreed also that no ruling on a medical question should be made by a local welfare commissioner in the absence of a definite recommendation by the medical director or the medical advisory committee. The State Department of Social Welfare agrees further to advocate the use of these committees, and the exact manner in which they should function will be outlined in a document to be prepared jointly by the Department and the State Medical Society."

This was recommended two years ago, but not agreed to by the Department of Social Welfare.

Under the second subdivision thereof, "All Physicians Should Be Encouraged to Participate in the Service," I quote

"It was agreed that the State Department's requirement, that a medical director or consultant be engaged wherever the plan is put in operation, would reduce lay interference in 'medical determination' to a minimum. It was pointed out, however, that the welfare commissioner is a layman who has sworn responsibilities which he may not renounce—including the authorization of welfare commitments—and that, while it is agreed that in medical matters he should have the advice and guidance of a medical director and/or committee of professional men medically competent, the responsibilities for decision must remain squarely on the shoulders of the commissioner and may in no sense be eliminated or considered as 'lay interference'."

Under the third subdivision thereof, "Utmost Decentralization of Control in Medical Matters," I quote

"Local supervising physicians or society boards should be able to rule on use of special drugs, use of consultants and specialists or any

other special treatment, without reference of these questions to State Department of Social Welfare

"Local welfare officers should have full authority to order special drugs and authorize special modes of therapy, with assurance of reimbursement to themselves, if approved by local supervising physician or society board"

Under the discussion of this third subdivision, there appears this paragraph

"Abolition of the system wherein medical questions are submitted to the State Department for decision is brought about automatically through introduction of the medical plan. It was pointed out that wherever the plan is installed and approved by the State Department the 'prior authorization' system is transferred to the local agency under local professional control. Under the new system professional members of the State Department staff will periodically examine the records of local agencies to determine whether or not the agency is adhering to the conditions established by themselves in their own plan"

This will obviate the delays and red tape heretofore interfering with adequate medical care

Under the fourth subdivision, "Free Choice of Physician Should Be Guaranteed Subject to Protective Limitations," authorization for medical care should be issued by local welfare officer and when possible on a fee-for-service basis

Under the fifth subdivision, "Contract Practice for Medical Relief Should Be Disapproved," the present system does not stop abuse of contract practice. The plan should, therefore, be given an opportunity of demonstrating the free choice of physician and fee-for-service basis, which is much superior to contract practice. The Local Welfare Board should be informed of the contrast between the two systems. It is the responsibility of the local medical profession to see that the system is changed by demonstrating the superiority of the fee-for-service basis. However, in no place in the state is there an adequate method of determining the total costs

I quote under the "Discussion"

"The Department cannot agree to this principle for the reasons stated under Principle No 4. It is quite obvious that if the Department finds the quality of care in a local community affected by and to the extent enumerated in Items 1, 2, and 3, under Principle No 5, and these conditions traceable to the use of salary or contract doctors, the Department would in its normal supervisory role insist upon a change in the system"

Under the sixth subdivision, "Clinics Should Not Be Exploited to Avoid Payment of Fees For Service. They Should Be Used When Medically Desirable," I quote from the discussion

"With the establishment of the local medical plan, the Department has no choice but to insist that existing clinics and other medical sources be used to the fullest, reasonable extent. The department does not, however, insist upon the use of such resources where they fail to meet the purpose for which they

were established. In determining jointly with the local welfare agency the extent to which clinics and other resources shall be used, the Department takes into consideration the quality of service, the scope of service, the physical facilities, and the ability of the clinic to handle qualitatively, as well as quantitatively, the number of cases to be referred by the local welfare agency"

This is a concession. Heretofore this has been obligatory, regardless of the capacity or facilities of the clinic

Under the seventh subdivision, "Provisions Should Be Made to Enable Needed Medical Care to Be Furnished for Indigent and Near Indigent Families Not Otherwise Eligible for Relief," medical indigency should be defined and placed in operation.

I move the acceptance of the first part of the report

The motion was seconded

SPEAKER BAUER This report summarizes very largely the report already printed in the Annual Reports which have been distributed to each of you. This summary is given to you in detail for your information, and the reference committee recommends the adoption of the principles which have already been approved by the Subcommittee on Medical Relief and by the Council. That is the substance of the recommendation of the committee. Is there any discussion on that portion of the report?

The question was called for, and the motion was put to a vote, and was unanimously carried.

DR VAN KLEECK As to a subsequent report, pertaining to direct payment to the Aged, the Blind, and for Dependent Children, again I quote from a joint statement by Christopher Wood, M.D., Chairman, Subcommittee on Medical Relief, and H. Jackson Davis, M.D., Chief Medical Officer, State Department of Social Welfare

"In the welfare districts in the state where physicians have heretofore been paid by the Welfare Department on a fee-for-service basis for authorized medical care given to persons receiving Old Age Assistance and Assistance to the Blind, a change effective April 1, 1941, has been made in the method of payment—so that such persons will pay physicians directly for such medical care given during the preceding month. This method has been used for some time in administering Aid for Dependent Children

"It was agreed by the representatives of the Medical Profession and the welfare officials that the installation of this plan would require careful preliminary interpretation and cooperative planning in each community"

The reference committee realizes that no definite recommendation can be taken at this time and feels that experience and data should be obtained.

Information has gone around the state that the State Medical Society "accepted" this change in system of payment for authorized medical care in these categories. That word is not accurate in this connection. The State Society neither *accepted* nor *rejected*, neither *approved* nor *disapproved*, but took the position

that it would go along with the State Department of Welfare to watch them after the change is made. The State Society representatives were very conscious that experience might be unsatisfactory, but until actual data could be obtained they did not feel that they could take a definite position for or against.

The reference committee believes that the Special Subcommittee on Medical Relief has accomplished many things that the State Society has striven for, for years. Their work is to be continued, and your reference committee recommends that the principles and policies agreed to by the Council and Department of Social Welfare be approved by this House of Delegates and that an opportunity be given to see how they work when in actual operation.

I move the adoption of this report, which is signed by myself as *chairman*, Samuel M. Allerton, Broome, George A. Burgin, Herkimer, W. Bayard Long, New York, and Charles A. Prudhon, Jefferson.

We do not make a recommendation on that subsequent report.

SPEAKER BAUER On the subsequent report relative to aid to the blind and old age security, what the report of the reference committee simmers down to is that the present method which has been adopted by the State Department of Social Welfare shall be tried out for a limited period in order to accumulate experience and data relative to it, and that no specific action for or against it should be taken at this time. Is that true?

DR. VAN KLEECK Yes, that in substance is what it amounts to.

SPEAKER BAUER Is there any discussion on that?

DR. CHARLES F. MCCARTY, Kings Kings County has made a definite recommendation that has been referred to one of the reference committees on this subject, and they will later make their report.

DR. VAN KLEECK Yes, that reference committee has not yet reported.

SPEAKER BAUER If that reference committee has a subject to report on which is much the same as this, I think it would be better to suspend action on this portion of the report until after that committee has reported so they can be acted on jointly, and unless there is objection by the House the adoption of this section of the report will be held in abeyance until after the other reference committee reports.

DR. VAN KLEECK To clear the atmosphere slightly, the reference committee now reporting realizes that no definite action can be taken on this at this time. We do not make a recommendation, but what we are making in effect is a motion to approve the report of the Subcommittee on Medical Relief.

SPEAKER BAUER The point I believe that Dr. McCarty made is that the other reference committee might have a definite recommendation which would conflict with that.

DR. VAN KLEECK Very well, I am satisfied to hold up this part of it until they make their report.

SPEAKER BAUER I think it would be better to suspend action on this until after we hear from the other reference committee, and then we will call on you again for the adoption of the balance of your report.

65 Presentation of Dr. Martin B. Tinker to the House

SPEAKER BAUER At this time before we proceed further there is one matter I want to call to your attention. There is a gentleman in the House who is a life member of this House, and who comes very often to our meetings, but hardly ever gets on his feet so that we have an opportunity to see him. He is celebrating an anniversary. He was President of the Medical Society of the State of New York twenty-five years ago, and I do not think that should go unnoticed. Therefore, I am going to ask Dr. Martin B. Tinker to arise.

The delegates arose and applauded. **DR. MARTIN B. TINKER, Tompkins** Mr. Chairman and Members of the House of Delegates, you all know that I am not a good speaker, but it would be unfair to let this opportunity pass without saying how much I appreciate the honor that was done by making me president of this great Society. It is a great responsibility too, as well as an honor. It has been a great pleasure to take a hand in the work of this Society over the years. There are so many of the men here now who worked with me year after year on the various committees of our Society. As I look back over the years, it seems to me that there has been very definite progress made.

It is a great pleasure, too, to see your friends and neighbors shifted along. From a child in the chair, Jim Flynn has become your president, further along the line, too, is our distinguished Cornell alumnus, Dr. Van Etten, then further along is Arthur Booth, and from my friends up in Buffalo I see Harry Trick. These men have all been presidents of our Society and have carried along the work. I did not mention Johnson over here, of Batavia. He is one of my oldest and best friends.

There is also the pleasure of seeing some of my former students. You get to feeling you are almost a grandfather when one of your boys, like Floyd Winslow, has become president of the State Medical Society, and another one of your pupils, like Van Kleeck, presents such a very good report as he has just presented.

So many of you, too, have sent me your friends and even your wives and children, which is a different sort of an honor and a different sort of responsibility. (Applause)

SPEAKER BAUER Thank you, Dr. Tinker!

66 Reconsideration of Disposition of Resolution Pertaining to Leaves of Absence for Officers in Military Service (Sections 28, 79)

SPEAKER BAUER Gentlemen, there was a resolution introduced in the House by Dr. West, for the First District Branch, which pertained to leaves of absence for officers of the State Society and District Branches who were in military service, and the Chair ruled this was an amendment to the Bylaws and could not properly be considered at this time. The Chair is still of the opinion that in its present form that is true, but it is realized that this is an urgent matter, and if we wait a year on it, it might make it entirely useless, so the Chair is going to refer this resolution to a reference committee, and will refer it to Dr. Masterson's Committee on New

Business C, with instructions that they call in the legal counsel, Mr Brosnan, and Mr Clearwater, the Society's attorney, to see whether or not by redrawing the resolution some way could be found to bring it within the framework of the Bylaws so that some action could be taken at this time

DR J LEWIS AMSTER, Bronx Point of information I think we could take care of this matter if we referred this resolution directly to this House of Delegates. By unanimous consent of the House I believe we could act on this resolution.

SPEAKER BAUER If it is against the Bylaws you cannot act on it even by unanimous consent of the House. However, it is possible that a way may be found, perhaps by a little rewording of the resolution, for the reference committee to act on it in the first instance, and it will come before the House as soon as the reference committee reports on it, but anything that is in violation of the Bylaws cannot be done even by unanimous consent

67. Report of Reference Committee on the Reports of the Secretary and District Branches

Secretary DR. STEPHEN R. MONTEITH, Rockland Your Reference Committee on the Report of the Secretary wishes to comment on the terse, concise nature of Dr Irving's report. We feel that, while this report must of nature be brief, it gives only a passing picture of the multitudinous activities and accomplishments of the Secretary and of the other departments under his able supervision as General Manager of the Society

Membership—Again your committee feels that it is necessary to comment on the increase in membership of the Medical Society of the State of New York. During the year 1940, a net gain of 624 members was made as compared with a gain of 608 in the year 1939. While this increase in the number of practicing physicians in the State of New York is not as great as that shown in the peak year of 1937, when 867 new members are shown, the total increase from 1935 through 1940 as shown by your Secretary's report reveals the alarming gain of 3,345 new physicians in practice in this state over this five-year period. We use the word "alarming" advisedly. Nowhere in the United States is the problem of the refugee physician or his close relative, the native-born graduate of foreign schools, more acute than in New York State.

Here, as shown by Dr Lawrence's comprehensive analyses of 1939, the ratio of physician to population at that time was 1 to 576. Now the ratio, we believe, for the state as a whole has decreased to the amazing figure of 1 to 476. With the present needs of the military branches of the Government forces being supplied wholly by graduates of schools in the United States and Canada, does this situation not present an alarming picture?

We wish here only to emphasize matters being opened for discussion by other committees

New York Office—The foresight shown in the moving of the offices of the Society to its present midtown location has proved a boon to those to whom operation of the Society's business has been entrusted.

The Council Committee on "Office Adminis-

tration and Policies" has functioned adequately and effects of its work are shown in the revamping of the business side of production of the *Directory* and *JOURNAL*. Mr Dwight Anderson has aided greatly in this work and in other matters of advertisement and publicity

The Policy Committee has instituted "Office Study" of several matters, notably the filing system necessary for proper compilations of biographical records of physicians and data used in preparation of the *Directory*. An analysis of the setup for handling these matters was entrusted to J. K. Lasser & Co., experts in this field

While carrying out their recommendations has entailed certain equipment expenditures (referred to by Dr Kosmak in his additional report this morning) it is felt by those in charge that these expenditures will yield dividends in further expediting this necessary work.

No doubt the position analysis (report of which will soon be made) covering the duties and compensations of the office force will also prove helpful in preventing overlapping of effort

Your reference committee feels that the business-like way in which the Council and its committees have approached the technical administrative problems incident to effective operation of the General Manager's office deserves only words of commendation from the House of Delegates, and we feel sure that each member of our Society appreciates the invaluable work done by our Administrative Officers

The fact that the office of Dr Kaliski, Director of the Bureau of Workmen's Compensation, is housed with the general offices, has helped both Dr Kaliski and Dr Irving, as well as kept them at all times available to members of the Society

Council Bulletins—Your reference committee notes that some delays have been experienced in publication of the "Bulletins of Council Proceedings." However, we are satisfied that unless the urgency of vital work prevents, these bulletins will appear promptly as directed. Certainly, these bulletins will have a coordinating effect on the work of the county societies and it is to be hoped that their appearance will be regular in the future

Coordination of Activity—The General Manager's Office has demonstrated its effective organization most notably in the manner in which it has handled the urgent problem of Medical Preparedness

Your committee feels that the Council Committee on Medical Preparedness has done its job with commendable care and with a spirit of devoted service. No doubt much of the effectiveness of this work has been due to cooperation received from Dr Irving and his office force, and to them we wish to express our thanks. Much work remains to be done in this field.

We feel that Organized Medicine in New York State under the inspired leadership so far exhibited will not be found wanting in maintaining a concerted effort in the medical care and protection of both our armed and civilian population in this time of national emergency

I move the adoption of this portion of the report

The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried

District Branches DR MONTEITH Your reference committee has noted with interest the reports of the several district branches. On the whole the attendance at the meetings held by these branches has been satisfactory, with one notable exception, the meeting of the Third District Branch. Due to confusion and delay in receiving the printed programs, notices of this meeting were sent out very late. This fact, no doubt, kept down the number of members present.

We wish to commend the officers of the First District Branch on their continuation of the custom of the past few years in conducting "clinic days" as part of their activity.

Your committee feels that the recommendations made by the House of Delegates last year tending toward development of the district branches into more cohesive organizations be continued. A new setup of each of these branches is desirable but your reference committee feels that for the present this matter had best be left to the judgment of the Council for its development.

I move the adoption of this portion of the report.

The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried.

DR. MONTEITH Now I move the report of the committee as a whole.

The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried.

68 District Branch Constitution and Bylaws (Section 52)

SPEAKER BAUER At this point, you will recall this afternoon that Dr West asked a question relative to the revision of the constitution and bylaws of the district branches, and the Chair answered that question and said if there was anything further he would consult Dr Lawrence and have him make a statement. What the Chair said was correct, but did not go quite far enough. There was another reason for the delay in the action on the constitution and bylaws of the district branches.

Dr Lawrence, will you just briefly add what I did not state this afternoon on this question so that Dr West and the other members of the House may be familiar as to why there has been delay in this matter?

EXECUTIVE OFFICER LAWRENCE The problem of the district branches is complicated in this way that heretofore the annual meetings have been primarily scientific meetings. Recently the activity of the Committee on Public Health and Medical Education has been extended in a much more satisfactory way than the district branches could go in the scientific field, so that there is an overlapping, with the result that it has been difficult for the district branches to prepare a scientific program with entirely new material.

The suggestion has been made—and it was placed before the Council—that the district branch program might be developed into a program of this character, and it is proposed to be tried in the Third District this year, that is, that the president, secretary, and chairmen of the various component county societies be invited

to attend the annual meeting, and at the same time the president, secretary, and chairmen of standing committees of the State Society be at the meeting, with the idea that the chairmen of the state committees and the county committees may have an interchange with regard to activities during the coming year and with regard to problems that may present themselves in the county societies. In this way we believe we can probably bring the state program to the county society in a way that it seems we should or an improvement over the present method at any rate. This, of course, will not include any scientific papers whatever. The Council thought that it would be well to have a trial of this. If it works out, we can recommend it for other district branches, but if it does not work out, we will not spoil too much at one time. I think that is what we had in mind.

SPEAKER BAUER Thank you, Dr Lawrence! I think that is purely informative. Does that answer your question, Dr West?

DR. THEODORE WEST, *First District Branch* Could I have the floor to make a few rebuttal remarks?

SPEAKER BAUER Yes, you may, Dr West, but it is not exactly rebuttal inasmuch as there is nothing before the House. It is purely a matter of information.

DR. WEST Perhaps I should say in explanation rather than in rebuttal, but never mind, the spirit is there if the words are bad.

It struck me when I got into the First District Branch to finish out the term of my predecessor that the district branch was organized about like nothing at all. There were no bylaws, there was no constitution. I did not know what I was supposed to do, what I was supposed to do it with, or why I was supposed to do it.

Carrying on the work of my predecessor, we got the scientific meeting going in the same way as he had started it, with great success, but at that time the economic condition throughout our district was getting rather acute—it still is acute, and I don't think it is getting any less acute—and the thing that struck me at that time was that the men in Rockland, and the men in Putnam, and the men in Dutchess, and the men in Staten Island, and all the rest of the counties in the district did not have the slightest conception of what problems confronted the other counties.

It seemed to me that a round-table discussion by the men who knew the problems of their own county throughout the counties of the district would bring the various counties of the district closer together, that they would find their problems were largely the same, and by working together they could do better work in trying to change bad conditions and get difficult situations corrected.

The present plan of having a meeting once a year or so with the State Society bringing its problems to the counties is splendid. I thoroughly approve of it, but I think in addition to that we need the district branches to know the problems of the various counties so that they can take them to the State Society.

That is where I think the present system may be a little weak. Without a constitution, without any bylaws, without any form of working, your district branch cannot function because it has nothing to function with or no plan to carry on.

For that reason I should like to ask the Council to speed up the work and to try, if possible, to get some sort of constitution to them to work out this plan, which in the First District is really working out, I believe, to the advantage not alone of the district and component counties in the district but which I believe redounds to the benefit of the state

I have taken a tremendous interest in this, and ask that the work be speeded up (Applause)

69 Report of Reference Committee on New Business B—Women Physicians for the Medical Reserve Corps of the United States Army and Navy

(Section 19)

DR. PETER J. DiNATALE, *Genesee* Mr Speaker and members of the House of Delegates, the Reference Committee on New Business B begs to submit the following report

On the resolution presented by the Medical Society of the County of New York, reading

"WHEREAS, the United States of America is at present engaged in a vast preparedness program which includes a listing of members in the Medical Reserve Corps available for active service, and

"WHEREAS there are approximately 8,000 women physicians and surgeons in the United States Women physicians and surgeons of America demonstrated their fitness for war-time service during the first World War when they financed units and staffed hospitals with well-trained officers, in France and Serbia, and

"WHEREAS, the United States Government has to date taken no cognizance of these women physicians in time of national emergency, and

"WHEREAS, the Government has already granted women nurses Army rating with proper rank, pay, and war-risk insurance, therefore be it

"Resolved, that the Medical Society of the State of New York recommend that the women physicians and surgeons of America be made eligible for the Medical Reserve Corps of the United States Army and Navy, and be granted full privileges thereof, and be it further

"Resolved, that the Medical Society of the State of New York instruct their delegates to the House of Delegates of the American Medical Association, that this request be laid before the House of Delegates of the American Medical Association for consideration" (Applause)

Your reference committee feels that women physicians have a place in our defense program and can be of great value in certain fields of service, and should be called upon for rendering service as they are capable of

They should have all the benefits, such as proper rank, pay, and war-risk insurance, as are allotted to other physicians

Your committee approves the resolution and moves its adoption (Applause)

The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried

DR. EMILY D. BARRINGER, *New York* May the women physicians thank you all very much

indeed There are a group of them meeting in this building this evening and I know they would send up their unanimous thanks if they knew of this action (Applause)

70 Report of Reference Committee on New Business B—Extending Invitation to American Medical Association to Hold Its 1944 Annual Meeting in New York City

(Section 29)

DR. PETER J. DiNATALE, *Genesee* On the resolution submitted by the Medical Society of the County of New York by Dr. Hellman, reading

"WHEREAS, the 1940 Annual Meeting of the American Medical Association was a great success in New York City, therefore be it

"Resolved, that the Medical Society of the State of New York extend an invitation to the American Medical Association to hold its 1944 Annual Meeting in New York City,"

Your committee approves that the meeting of the American Medical Association be held in 1944 in New York City, providing that the New York State Medical Society meeting is held in some other city, because we feel that attendance at the New York State Medical Society meeting is reduced when both meetings are held the same year in New York City

I move the adoption of the report of the reference committee.

The motion was seconded

SPEAKER BAUER The reference committee's report is rather predicated on something that has not yet been decided. I wonder if the committee can make a little more concrete recommendation.

DR. DiNATALE What meeting has not been decided upon?

SPEAKER BAUER Where the meeting of the Medical Society of the State of New York will be held in 1944 has not been decided on. True, we usually go to New York City in alternate years, so in all probability in 1944 the meeting would be held in New York City. The point of the resolution I think could be brought out if the committee extended an invitation for a future year, or if they recommended definitely that the invitation be extended and that the meeting of the State Society be not held in New York that year. I think you have to have a definite recommendation, not predicated on something that has not yet been decided

DR. ALFRED M. HELLMAN, *New York* As the maker of that resolution may I amend it to read 1945? It is customary to hold the State Meeting every other year in New York City, and that would bring it to New York City in 1944

SPEAKER BAUER The only point about that amendment would be this, Dr. Hellman. There would be no point in presenting such a request to the House of Delegates of the American Medical Association for 1945, as they select the meeting place three years ahead, and the 1944 meeting place would be the one selected this year

DR. HELLMAN I withdraw my amendment

SPEAKER BAUER As I understand it, the way the resolution now reads is that the State Society should extend an invitation to the American Medical Association to meet in New York City in 1944?

DR DiNATALE Right!

SPEAKER BAUER And that the State Society meeting should not be held in New York City at that time, is that right?

DR. DiNATALE That was the feeling of the committee. In view of the experience last year, we thought the attendance at the State Meeting was held off because a lot of the doctors waited for the American Medical Association meeting in New York City. We wondered whether it was a wise policy to hold the two meetings in the same year in the same city.

DR. HARRY ARANOW, Bronx Why not make the invitation to the American Medical Association, and then if it is accepted the State Society will decide for itself whether it wants to hold its meeting in New York that year or not?

SPEAKER BAUER You suggest then, I take it, that this motion be separated and that it be amended to read that the invitation be extended to the American Medical Association for 1944, without any strings attached to it.

DR. ARANOW Yes

SPEAKER BAUER Do you make that as a motion?

DR. ARANOW I do

The amendment was seconded.

SPEAKER BAUER The question then is on the amendment to the committee's report, that is, that the matter of the 1944 New York State Society meeting place be eliminated, and that an invitation be extended to the American Medical Association to meet in New York City in 1944.

Is there any discussion on the amendment?

DR. JOHN J. BUETTNER, Onondaga Undoubtedly, the attendance last year was influenced by the fact that the World's Fair was being held in New York. Possibly with no World's Fair being present in 1944, it may make a difference.

The question was called for on the amendment, and the motion was put to a vote, and the amendment was unanimously carried.

SPEAKER BAUER You now have before you the amended motion for adoption.

The question was called for, and the motion was put to a vote, and the amended motion was unanimously carried.

71 Report of Reference Committee on New Business B—Corporate Practice of Medicine (Section 28)

DR. PETER J. DiNATALE, Genesee On the resolution presented by the Medical Society of the County of Westchester on the Corporate Practice of Medicine, reading

"WHEREAS, the practice of medicine or of any other profession by a corporation is advisedly prohibited by most of the States of the Union, and

"WHEREAS, New York State now authorizes the formation of nonprofit corporations in the field of voluntary health and medical expense insurance, a development which may ultimately be extended to the authorization of the virtual practice of medicine by commercial as well as nonprofit corporations, and

"WHEREAS, proponents of radical innovations in the practice of medicine are known to be seeking means of breaking down or of circumventing present legal obstacles to the out-

right or disguised practice of medicine by corporations, therefore be it

"Resolved, that the House of Delegates request the Council to designate a committee to study the present laws and precedents in New York State relating to the corporate practice of medicine, this committee to be charged with the continuing duty of studying and periodically reporting to the House of Delegates and to the Society its findings and recommendations, with a view to preventing the destruction or circumvention of legal safeguards against corporate practice in New York State."

your committee feels that the Council and duly elected officers should at all times be cognizant of any impending legislation and be on the alert to study the same

Your committee approves the resolution and moves its adoption.

The motion was seconded, and as there was no discussion, it was put to a vote and was unanimously carried.

72 Report of Reference Committee on New Business B—Medical Relief—Ambulatory Care (Section 54)

DR. PETER J. DiNATALE, Genesee On the resolution introduced by the Bronx County Medical Society on the Care of the Indigent, reading

"WHEREAS, the indigent of the City of New York are provided with medical care through a plan devised by the Medical and Nursing Service for Home Care, and

"WHEREAS, these same indigents require ambulatory care for which no provision is made, and

"WHEREAS, the physicians of the City of New York are supplying this ambulatory care without remuneration, be it

"Resolved, that the Bronx County Medical Society recommend that provisions be made for the ambulatory care of indigent patients in the office of the private practitioners and that the physicians be adequately remunerated for this care, and be it further

"Resolved, that these resolutions be introduced at the House of Delegates at the meeting of the New York State Medical Society in April, 1941,"

the Reference Committee on Business B approves the resolution as read. I so move

The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried

73 Report of Reference Committee on New Business B—Medical Relief—Direct Payment of Medical Fees to the Aged, the Blind, and Dependent Children (Sections 22, 23, 33)

DR. PETER J. DiNATALE, Genesee In regard to the resolutions as proposed by the Medical Society of the County of Kings, reading

"WHEREAS, under existing laws, it is the duty of the State to provide medical care for those persons who are unable to provide this care for themselves, and

"WHEREAS, the cost of medical care is var-

able and, at the present time, cannot be estimated in advance, and

"WHEREAS, under the Social Security Act payments for assistance in categories for which grants are given by the Federal Government, such as the aged, the blind and dependent children, can be made only to the recipient of this assistance, and

"WHEREAS, under this ruling physicians treating persons receiving old age assistance, aid to the blind or aid to dependent children can no longer be paid directly by the local welfare organizations, and

"WHEREAS, physicians, nurses, appliance dealers, etc., have no accurate knowledge of when persons in these categories receive checks to pay for medical services which physicians and others have given them, and

"WHEREAS, this tends to cause additional hardship to physicians and others by either requiring them to go to the patient's home, possibly several times to collect their fee, or to treat these patients without just recompense, and

"WHEREAS, we realize that the Subcommittee on Medical Relief of the State Medical Society, the New York State Department of Social Welfare, and the New York City Department of Welfare feel that persons rendering medical care of New York State should be paid directly but that the State could not sacrifice approximately \$900,000 per year in Federal grants for medical care which they must sacrifice under this provision of the Social Security Act if the monies were paid to other than the recipients-of-aid in these categories, therefore be it

"Resolved, that the Medical Society of the State of New York, through its Delegates to the American Medical Association, request that the American Medical Association have legislation initiated to provide a change in the Social Security Act so that persons rendering medical care to recipients-of-aid from any government agency may be paid directly by that agency,"

and the Medical Society of the County of New York, reading

"WHEREAS, after April 1, 1941, checks from the Department of Welfare of the State of New York (Q V Form M med 383 b) for the Medical Care of those patients entitled to Old Age Assistance and Blind Assistance will be issued directly to the recipients of the care and not to the doctors rendering it, and

"WHEREAS, this forces the physician to collect these fees from indigent people who may be unreliable, therefore be it

"Resolved, that the Medical Society of the State of New York go on record as being opposed to the proposed change in method of payment, and that the Society request the Department of Welfare to continue its former method of paying these physicians directly,"

and we have two letters from the Medical Society of Broome County and from the Medical Society of Wyoming County on the same subject, which strictly speaking are not resolutions but are merely informative, your reference committee has taken the following stand

Your committee feels that these resolutions

are in the main identical, and that they both are in contradiction to the study and plans evolved by the joint committees on Medical Relief of the Medical Society of the State of New York and the New York State Department of Social Welfare

This committee feels after a study of the joint plans that the plan should be given a fair opportunity of being put into effect

The joint plan states that the representatives of the Medical Society of the State of New York and the State Department of Social Welfare agreed that the medical features of the program would be subject to a careful review after six months of operation to determine

- 1 Whether or not the anticipated savings materialize,
- 2 Whether there are difficulties in the operation of the direct payment plan, which cause individual physicians or local welfare officers concern

Both the State Department of Social Welfare and the Medical Society of the State of New York will be glad to review and make every effort to solve any locally unresolved problems encountered in the installation and operation of the "Direct Payment Plan" if the specific problems, with identifying details, are submitted to the proper authorities

In view of the above joint statement in part, your reference committee feels that the resolution of the Medical Society of the County of New York and the Medical Society of the County of Kings be disapproved.

I move the adoption of the report of the reference committee

The motion was seconded.

DR. DiNATALE I believe that the reference committee of which Dr. Van Kleeck is chairman has also considered this subject, and has a recommendation to make on it

SPEAKER BAUER That portion of his report has not been acted upon, but has been held in abeyance pending the report of this reference committee on that subject

DR. LOUIS A. VAN KLEECK The Reference Committee on the Report of the Council, Part VI, recommended that no action be taken

SPEAKER BAUER You have before you the recommendation of the reference committee which carries with it the disapproval of both the resolutions, and recommends that a trial be given to the plan which has been promulgated by the Department of Social Welfare in order to accumulate experience on that plan. It is in substance the same recommendation that Dr. Van Kleeck made in his committee's report a short while ago, and which we held in abeyance pending the report on these resolutions and letters

DR. VAN KLEECK Yes

SPEAKER BAUER Is there any discussion on the Reference Committee on New Business B's report?

DR. LEO F. SCHIFF, Clinton It seems to me it would be a bad thing for this State Society to go on record as disapproving of these resolutions. There is another course which can be taken, and which would be consistent with the action taken on Dr. Van Kleeck's report, and that would be to recommend that no action be taken on these resolutions. It would not be approving them and still it would not be disapproving them.

I would suggest to the committee chairman that if he cares to change his recommendation at this time it would be the simplest way out of it without recording ourselves as disapproving something which might leave us open to a misunderstanding later.

DR. DiNATALE: Your chairman will gladly accept the recommendation as made by Dr Schiff in regard to these resolutions.

The seconder acquiesced in the suggestion.

SPEAKER BAUER: The motion before you, then, is that no action be taken on these resolutions at the present time, but that an opportunity be given to see how the plan already in operation will work out.

Is there any further discussion?

DR. VAN KLEECK: In regard to this, as I understand it, the trouble here is that if the payment is made by the welfare officer to the doctor there is an allocation of federal money that will be lost. Am I right so far?

SPEAKER BAUER: That is true.

DR. VAN KLEECK: The State of New York pays a large amount into this fund, and it gets back again money from the federal fund. Am I right there?

SPEAKER BAUER: A certain amount.

DR. VAN KLEECK: At any rate it pays a larger amount into this fund than other states do?

SPEAKER BAUER: Yes.

DR. VAN KLEECK: My committee was afraid of that feature. If we want the welfare officer to pay the doctor, then they lose \$900,000 a year in this state. Am I right there?

SPEAKER BAUER: That is correct.

DR. VAN KLEECK: Is Dr. Christopher Wood here?

DR. MERWIN E. MARSLAND, *Westchester*: No, he has been called out.

DR. VAN KLEECK: He made the statement when he appeared before the reference committee that physicians should give this plan a trial, that is, where the money is given to the blind or agent of the dependent children directly, and establish with them a sort of independent feeling that will encourage them to pay their own doctors' bills. Furthermore, it is more or less conceded that they will do so.

If the physician does not receive his pay for services rendered to those people he will confer a favor upon this special subcommittee of the Council if he will so inform his county society and they in turn communicate the poor results he has had to the subcommittee. Do I make myself clear on that?

CHORUS: Yes.

DR. VAN KLEECK: For statistical purposes, the special subcommittee, which is going to continue on with this work wishes the information as to whether or not the doctors are experiencing any difficulty in receiving payment direct from the people who receive the medical care. I approve the recommendation of my committee, and Dr. Schiff's suggestion, that no action be taken on these resolutions.

SPEAKER BAUER: Is there any further discussion?

DR. JAMES GREENOUGH, *Otsego*: It seems to me that there is a difference between these two resolutions that have been presented to us.

The first one is to ask the American Medical Association to ask the Federal Government to remove this stipulation. The second one is to ask the State Welfare Department to remove it.

Would there be any reason why the delegates to the American Medical Association should not ask the Federal Government to remove this prerequisite?

SPEAKER BAUER: Do you wish to make any motion in regard to it?

DR. GREENOUGH: I should like to amend the recommendation of the reference committee so that it will approve the first resolution that was read instructing the delegates of the State Medical Society to the American Medical Association to institute proceedings there to change the action of the Federal Government in enforcing this requirement.

The motion was seconded by several.

SPEAKER BAUER: It has been moved and seconded that the Report of the Reference Committee on New Business B be amended to the effect that the first resolution which was introduced—I believe by the County of Kings?

DR. DiNATALE: Yes.

SPEAKER BAUER: To memorialize the American Medical Association to take steps to have the law changed so that the states would not be penalized if they made direct payments to the doctors, be approved, and that no action be taken on the other resolution.

DR. DiNATALE: The reference committee felt, in view of the fact that the plan as it had been worked out by the Subcommittee on Medical Relief of the Council in joint meeting with the State Welfare Department had had no opportunity to be tried out, to ask for a change without giving the plan a fair trial was not the proper thing to do.

DR. DAVID J. KALISKI, *New York*: I think there is some misapprehension about the stand of the State Medical Society and the local county societies on this proposal. There was no hesitation on the part of the State Welfare Officers, I believe, in stating that they did not favor the principle that the money should be paid directly to the relief recipients, but it was a portion of the law and it had to be carried out as it was statutory.

In order to meet this statutory requirement, they requested the State Society to try it out for a period of time, and the State Society, although it objected to the principle of paying the recipient directly rather than the doctor, agreed to make the trial over a period of about six months.

Therefore, I don't think there is anything antagonistic in the resolution asking the Federal Government to change the law in regard to the direct payment to recipients for medical care.

Secondly, I think that the local county societies in the metropolitan area very strongly resisted the trial, although they were forced to carry on with the State Medical Society because of the fact that in certain parts of the state it was apparent that relief recipients—old age recipients rather—were paying their doctors in the majority of instances, but I don't believe that we could say if we passed the first resolution we are going counter to anything that the State Medical Society Committee agreed upon.

DR. F. LESLIE SULLIVAN, *Schenectady*: It seems to me that the further we go on with the

discussion of these resolutions the more confused we get. It has always been the aim of this Society in the past—and I think it is one of the ideals that we relish—to maintain a direct doctor-patient relationship. We have stressed that in New York State, we have stressed it in all the states of the Union that the doctor and the patient must not be divided, but they must be directly related.

Secondly, through the work of this Subcommittee on Medical Relief the doctors of this state have the opportunity to have a hand in the administering of this type of work. They also have an opportunity to take care of the abuses that might arise from a direct-payment system, if we believe that such should be administered.

I don't believe that a resolution from this House to the American Medical Association, asking them to prepare legislation to amend this section of the public welfare law so that direct payment may be made to the doctor for care is consistent with the policy that we wish to follow. Further, this committee conducted its negotiations in the belief that the House still desired that the relationship between the doctor and his patient should be undisturbed.

In the administration of relief for dependent children, it has been found that the abuse of the direct-payment system has been less than 2 per cent, and I think that, consistent with the recommendation of the Subcommittee on Medical Relief, we can give them an opportunity over a six months' period to find out whether or not this thing will work.

SPEAKER BAUER Is there any further discussion on the amendment? If not, the question is on the amendment. The amendment is that the committee's report be changed to provide that this resolution shall be passed memorializing the American Medical Association to take efforts to have the Social Security Law changed.

The question was called for, and the amendment was put to a vote, and was lost.

SPEAKER BAUER The question is now on the recommendation of the reference committee as amended by Dr Schiff, and as accepted by Dr DiNatale, the chairman of the reference committee, that no action be taken on these resolutions. Is there any discussion on that?

The question was called for, and the motion was put to a vote, and was carried.

74 Report of the Reference Committee on New Business B—Medical Preparedness—Funds for County Society Committees (Section 21)

DR. PETER J DiNATALE, Genesee On the resolution, as presented by the Medical Society of the County of Kings, reading

"WHEREAS, the American Medical Association and the Medical Society of the State of New York have agreed to assist the Federal Government in National Defense, and

"WHEREAS, this has necessitated the selection of over 2,000 physicians in New York State to work on Local Draft Boards and Medical Advisory Boards, and

"WHEREAS, selection and recommendation of physicians to serve on these Boards has necessitated innumerable telephone conferences and correspondence, and

"WHEREAS, requests are constantly being made of the county medical societies by both the State Medical Society and the Army as to the capacity of physicians to do certain types of work, and

"WHEREAS, we are now being requested to review the records of and to certify the 4,600 doctors of Brooklyn as to their availability for military or naval service, or as to their need for the care of the civilian population, and

"WHEREAS, this is an added burden on already overburdened clerical and stenographic staff in the county medical societies, therefore be it

"Resolved, that the New York State Medical Society allot sufficient funds to the county societies to provide additional necessary clerical and stenographic help and office equipment to assist in carrying on the work of the committees on medical preparedness,"

your reference committee felt that as this was really work asked for by the American Medical Association, by doctors of doctors, this resolution should be changed to read

"That the Medical Society of the State of New York allot sufficient funds to assist the county committees on medical preparedness where it is evident that such assistance is needed."

The resolution, as amended, is approved by your reference committee. I move its adoption as so amended.

The motion was seconded.

SPEAKER BAUER You have before you the report of the reference committee, which is amending the original resolution, providing for the allotment of funds by the State Medical Society where such assistance is deemed necessary. Is there any discussion on that report?

DR. GEORGE W. KOSMAK, New York This seems to me a very indefinite proposition. We do not know how much assistance will be needed by these individual county societies. I think if we are to extend such aid a much more definite and detailed proposition should be put before us. My God, you cannot tell where this is going to end up. (Applause)

DR. HAROLD J. HARRIS, Essex I do this work for our county society, Essex. It is a small one, but it is work that physicians have to do. I cannot see where clerical hire or office equipment comes into it. I think in any county it is a matter of physicians judging the qualifications of other physicians, and I do not see how we can employ clerical hire to do that for us. (Applause)

DR. FREDERIC E. SONDERS, New York Mr Speaker and Gentlemen, I think it is a pretty well-established rule that the House of Delegates cannot vote any money for any purpose. Therefore, if you are going to pass any resolution like this you are going to recommend to the Board of Trustees and not vote the money.

I am "agin" it down in my heart, but if you are going to do it, don't do it directly but recommend it to the Trustees, and let them be the judges. (Applause)

SPEAKER BAUER Dr. Sonders's point of order is correct. Expenditures must be recommended to the Board of Trustees.

DR. JOHN J. MASTERSON, Kings I am sorry Dr. McGoldrick is not here, he is evidently

downstairs on a reference committee. In Kings County, where I happen to be chairman of the board of trustees, we have had to spend some real money for this work. We have had to hire additional quarters, we have had to hire a typewriter, we have had to buy a desk, we have had to buy some files, and we have had to hire a stenographer.

Dr. Kosmak said, and properly so, that they should know how much the various county societies need. Well, we don't know ourselves how much we will need because we don't know how much work we are going to do.

I think some provision should be made whereby this House of Delegates or some other body has the power to say whether our money shall be expended or not, and not the Board of Trustees alone, because I think if only the Board of Trustees has the power to say whether money shall be expended or not, then the Board of Trustees is the State Society when it comes to funds, and not the House of Delegates, or the body itself.

In the large counties this is a serious question. We cannot lay down on the job in Kings because we have had to spend this money. We want to do our part. We have received a questionnaire to send to all the hospitals in the city asking how many men they will require on their staff. We have got to get in contact with all those medical reserve officers who have not responded to the questionnaire, and if anybody does not think that is real work in a county of 4,500 men they are mistaken.

We are spending money which we feel either the State Society or a state or federal agency should do the spending on, and not us.

SPEAKER BAUER: For the information of the House I will read the last sentence of Chapter IX of the Constitution.

"The approval of the Council and of the Board of Trustees shall be necessary for the expenditure of any funds of the Society."

DR. HARRY ARANOW, *Bronx*: I make an amendment to the effect that this be referred to the Council for determination of the amount at the time such expenditure is deemed necessary.

SPEAKER BAUER: That is not properly an amendment, but I will take it as a motion to commit.

DR. HARRY ARANOW: Very well!

SPEAKER BAUER: Dr. Aranow moves that the matter be referred to the Council for action.

DR. LOUIS A. VAN KLEECK, *Nassau*: I second that.

SPEAKER BAUER: Is there any discussion on the motion to commit?

DR. EDWARD T. WENTWORTH, *Monroe*: I don't like that because I don't see where the money is coming from. Granted that Kings County may need assistance, I cannot quite see how Lewis County should assist them or why they should have to assist them.

Possibly the Federal Government should pay this bill, but if it does not I cannot see at all why the Medical Society of the State of New York should pay it.

If the matter is referred to the Council, as that motion, or amendment, or whatever you termed it, indicates, it rather carries the mandate with it that the Council has to find this money.

SPEAKER BAUER: No, the motion was to commit the whole matter to the Council to determine what should be done with it, not that they were directed to spend any funds. It was referred to the Council to decide how the matter should be handled.

DR. WENTWORTH: If that's the case, I am satisfied.

DR. DAVID J. KALISKI, *New York*: I may be able to give some information about certain reduplication of work in this connection. There is a Joint Committee of the Hospital Association and the Medical Profession in regard to selective service and medical reserve officers who may be required in the defense program or in the eventuality of war. This matter was brought to the attention of the group of which Dr. Rappleye is chairman and the president of the Hospital Association is a member, and I believe that they are now making a survey of all of the hospitals to indicate the number of men who will be required to carry on under any eventuality, the number of men who are members of the Medical Reserve Corps, the number of such men who may be called into service, and other pertinent facts in this connection.

It may be that the Kings County Medical Society and other county societies are not aware that such a survey is being made by the Joint Committee of the Hospital Association and the Medical Profession, which may make it unnecessary for Kings County Society and the other county medical societies to make a considerable part of this survey.

DR. MERWIN E. MARSLAND, *Westchester*: Mr. Speaker, this is only a suggestion. These examinations are made by physicians, as I understand it, without recompense, am I right?

DR. MASTERSON: Right.

SPEAKER BAUER: You are right.

DR. MARSLAND: They are made in communities that have some degree of public spirit, and probably within a short time will have more. In certain localities the local hospital has supplied the clinic rooms and secretaries and nurses to aid in these examinations. The doctors of the local medical societies have not had to pay out any money. Why is it not possible that in these communities where it is a financial problem the interest of some public organizations be aroused? Perhaps they don't know about it, and they would be glad to volunteer their services as secretaries, clinic aides, etc. They frequently do to the usual clinics in their locality.

DR. MASTERSON: This work that the various county societies are doing I understand has been taken up at the request of the State Medical Society, is that not correct? We are not asking Lewis County or any other county to help pay the expenses incurred by our society in doing this work. We are paying into the State Society nearly \$30,000 a year. There is no more reason why we should dig into our surplus than the State Society. We should not have to dig into our surplus to pay for this, and if we are forced to, why should not the State Society help us?

This expenditure of money is not in relation to the examinations. This expenditure of money is for a clerk, room hire, and office furniture. We have in our county about 100 boards. We have twelve medical advisory boards. These

people are calling up on the telephone all day long for information. We must have somebody there to answer the telephone. We are not asking any money for the time given by the doctors, but only for the actual expenditure of money that we are compelled to pay out to do this work.

DR. ARANOW. A point of order, Mr. Speaker. I made a motion to commit, and all the discussion has been on something which is entirely different.

SPEAKER BAUER. The motion before the House is on committing this resolution to the Council for such action as they may find expedient.

DR. JOHN L. BAUER, *Kings*. I am a bit puzzled by the need of a motion to commit or by the interpretation given to our Constitution and Bylaws. It seems to me that the House of Delegates is the whole, and that the Council and Board of Trustees are just part of this House, and I see no reason in the world why any other interpretation should be given this than that this House of Delegates can decide this question now as to what they, themselves, want done.

SPEAKER BAUER. The motion before you is on the commitment. Is there any further discussion? If not, all those in favor of committing this resolution to the Council will say "Aye", opposed, "No". The Chair is in doubt. Those in favor of committing the resolution will please stand and remain standing until counted. Now those opposed will please stand and remain standing until counted. The motion to commit is carried by a vote of 67 to 45. (Applause)

Have you any other resolutions?

DR. DiNATALE. Yes, I have two dandies coming up. (Laughter)

75 Report of Reference Committee on New Business B—Licensure—Standards for Recognition of Foreign Medical Schools

(Section 14)

DR. PETER J. DiNATALE, *Genesee*. On the resolution presented by Dr. Winslow, reading

"WHEREAS, any historical review of the development of medical licensure in the State of New York brings into prominent relief the important role that the Medical Society has assumed in each step of that development, the Society having initiated movements from time to time to raise the requirements for licensure with the sole objective in view to provide for the people of the state the very best quality of medical care available, and

"WHEREAS, the existing requirements for medical licensure if properly enforced within the intent of the law will provide ample protection to the people from the ministrations of incompetent practitioners so far as any law can afford that protection, and

"WHEREAS, a student from the United States or Canada is required to present evidence that he has completed not less than four satisfactory courses of at least eight months each in a medical school in this country or Canada registered as maintaining at the time a standard satisfactory to the Department, or has received the degree of bachelor or doctor of medicine from some medical school in this country or Canada, registered as main-

taining at the time a standard satisfactory to the Department, and

"WHEREAS, a determination of the reputability and good standing of medical schools in the United States and Canada is on a sound basis by reason of periodic inspections of such schools by the Department of Education of New York State, the Council on Medical Education and Hospitals of the American Medical Association and the requirements for membership in the Association of American Medical Colleges, but the Department has available no comparable evidence with respect to medical schools located elsewhere because of the fact that no agency exists in this country which inspects or classifies such foreign schools, and

"WHEREAS, despite this lack of authentic information as to the quality of instruction given in foreign schools, graduates from such schools are in increasing numbers receiving licenses to practice medicine in New York State, and

"WHEREAS, according to the statistics furnished by the Bureau of Immigration of the United States, the influx of graduates of foreign medical schools into the United States has increased from 329 in the fiscal year ending June 30, 1931, to a total of 1,384 during the fiscal year ending June 30, 1939, making a total of 4,549 for the same period, a large majority of whom have been licensed in this and other states, and

"WHEREAS, the ethical and professional fitness of a candidate for medical licensure cannot be appraised solely on the strength of an examination but must be gauged also by the quality of instruction that the applicant has received during his pre-professional and professional schooling, and

"WHEREAS, the foregoing situation presents a continuing menace to the health and welfare of the people of New York State and thus constitutes a problem causing great concern to the medical profession of the state, be it therefore

"Resolved by this House of Delegates

"(1) That recognition for medical licensure in New York State, whether after examination or otherwise and irrespective of the question of citizenship, of graduates of foreign medical schools be strictly in accordance with the method of recognition that is applied with respect to the graduates of medical schools located in the United States and Canada. Any other method of recognition would constitute the grossest type of discrimination in favor of foreign graduates,

"(2) That in the future recognition be accorded graduates of a foreign medical school who apply for license to practice medicine in the State of New York, only when there is in the possession of the Department evidence of the quality of instruction imparted by the school of graduation. This must be of equal quality with the evidence required of approved domestic schools. The identical standard should be applied in approving all medical schools, domestic or foreign."

after considerable study your reference committee approves the resolution as read and moves its adoption

downstairs on a reference committee. In Kings County, where I happen to be chairman of the board of trustees, we have had to spend some real money for this work. We have had to hire additional quarters, we have had to buy a typewriter, we have had to buy a desk, we have had to buy some files, and we have had to hire a stenographer.

Dr. Kosmak said, and properly so, that they should know how much the various county societies need. Well, we don't know ourselves how much we will need because we don't know how much work we are going to do.

I think some provision should be made whereby this House of Delegates or some other body has the power to say whether our money shall be expended or not, and not the Board of Trustees alone, because I think if only the Board of Trustees has the power to say whether money shall be expended or not, then the Board of Trustees is the State Society when it comes to funds, and not the House of Delegates, or the body itself.

In the large counties this is a serious question. We cannot lay down on the job in Kings because we have had to spend this money. We want to do our part. We have received a questionnaire to send to all the hospitals in the city asking how many men they will require on their staff. We have got to get in contact with all those medical reserve officers who have not responded to the questionnaire, and if anybody does not think that is real work in a county of 4,500 men they are mistaken.

We are spending money which we feel either the State Society or a state or federal agency should do the spending on, and not us.

SPEAKER BAUER: For the information of the House I will read the last sentence of Chapter IX of the Constitution.

"The approval of the Council and of the Board of Trustees shall be necessary for the expenditure of any funds of the Society."

DR. HARRY ARANOW, *Bronx*: I make an amendment to the effect that this be referred to the Council for determination of the amount at the time such expenditure is deemed necessary.

SPEAKER BAUER: That is not properly an amendment, but I will take it as a motion to commit.

DR. HARRY ARANOW, *Very well*.

SPEAKER BAUER: Dr. Aranow moves that the matter be referred to the Council for action.

DR. LOUIS A. VAN KLEECK, *Nassau*: I second that.

SPEAKER BAUER: Is there any discussion on the motion to commit?

DR. EDWARD T. WENTWORTH, *Monroe*: I don't like that because I don't see where the money is coming from. Granted that Kings County may need assistance, I cannot quite see how Lewis County should assist them or why they should have to assist them.

Possibly the Federal Government should pay this bill, but if it does not I cannot see at all why the Medical Society of the State of New York should pay it.

If the matter is referred to the Council, as that motion, or amendment, or whatever you termed it, indicates, it rather carries the mandate with it that the Council has to find this money.

SPEAKER BAUER: No, the motion was to commit the whole matter to the Council to determine what should be done with it, not that they were directed to spend any funds. It was referred to the Council to decide how the matter should be handled.

DR. WENTWORTH: If that's the case, I am satisfied.

DR. DAVID J. KALISKI, *New York*: I may be able to give some information about certain reduplication of work in this connection. There is a Joint Committee of the Hospital Association and the Medical Profession in regard to selective service and medical reserve officers who may be required in the defense program or in the eventuality of war. This matter was brought to the attention of the group of which Dr. Rappleye is chairman and the president of the Hospital Association is a member, and I believe that they are now making a survey of all of the hospitals to indicate the number of men who will be required to carry on under any eventuality, the number of men who are members of the Medical Reserve Corps, the number of such men who may be called into service, and other pertinent facts in this connection.

DR. MERWIN E. MARSLAND, *Westchester*: Mr. Speaker, this is only a suggestion. These examinations are made by physicians, as I understand it, without recompense, am I right?

DR. MASTERSON: Right.

SPEAKER BAUER: You are right.

DR. MARSLAND: They are made in communities that have some degree of public spirit, and probably within a short time will have more. In certain localities the local hospital has supplied the clinic rooms and secretaries and nurses to aid in these examinations. The doctors of the local medical societies have not had to pay out any money. Why is it not possible that in these communities where it is a financial problem the interest of some public organizations be aroused? Perhaps they don't know about it, and they would be glad to volunteer their services as secretaries, clinic aides, etc. They frequently do to the usual clinics in their locality.

DR. MASTERSON: This work that the various county societies are doing I understand has been taken up at the request of the State Medical Society, is that not correct? We are not asking Lewis County or any other county to help pay the expenses incurred by our society in doing this work. We are paying into the State Society nearly \$30,000 a year. There is no more reason why we should dig into our surplus than the State Society. We should not have to dig into our surplus to pay for this, and if we are forced to, why should not the State Society help us?

This expenditure of money is not in relation to the examinations. This expenditure of money is for a clerk, room hire, and office furniture. We have in our county about 100 boards. We have twelve medical advisory boards. These

Your committee wishes to advocate an expression of thanks and appreciation to the Governor for this veto action.

At this time the Governor has in his hands a bill providing that violations of the Medical Practice Act can be heard by a subcommittee of the Grievance Committee with a later confirmation by two-thirds vote of the full committee. We hope that the Governor will approve this measure.

Your committee approves of the stand of the Committee on Legislation to safeguard the use of the title of "Doctor" by those who practice podiatry, and that measures be taken to enact legislation to limit the term "Doctor" to those who deserve it without qualifying terms.

Your committee approves of the suggestion of the Committee on Legislation for the early introduction and aggressive canvassing of individual legislators in reference to the Physicians' Lien Bill, the Radiology Bill, and the bill for medical expert testimony in personal injury litigation.

We are impressed by the efforts of the Committee on Legislation and our Executive Officer in defending constructive medical legislation.

Our Society has always been very successful in its opposition to vicious legislation, however, our efforts to pass legislation have not always resulted in favorable action. This has frequently been due to the lack of united support to the bills introduced in the Legislature. Opposition has frequently come from individual members of our Society. This has always been permitted. In spite of the fact that the Society has gone on record against opposition from a component society except when contrary opinions are held they be referred to your State Committee on Legislation, instances have occurred when component societies have been engaged in active opposition to the decision of the State Society. These contrary opinions have been presented to the State Legislators.

Your Committee wishes to express its confidence in the constructive activities of our executive officer in connection with his legislative duties and commends the Committee on Legislation for their alertness during the past year.

I move the adoption of this report.

The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried.

Malpractice Defense and Insurance. Dr. CUNIFFE. The reference committee reviewed and the Council approved the report of the Committee on Malpractice Defense and Insurance of which Dr. Bandler is chairman.

The committee notes that during the eleven months covered by the report the number of suits and claims against members of the Society and the cost of disposing of them has remained substantially the same as in 1939.

It is noted that a revision of the rate scale for malpractice insurance may be recommended with an increase in the case of the minimum limit policy and a decrease for the higher limits, thereby making the premium charges commensurate with the actual costs of operation.

The following extract from the report is especially called to the attention of the membership:

"As in previous years, it is noted that loose, unwarranted and frequently thoughtless criti-

cism by fellow-members of their confreres continues to be the largest single inspiration for malpractice actions. This is a phase of medical practice which can and should be vigorously attacked in every community."

The fact that during the past year 35 malpractice claims were brought against noninsured members is a strong argument for every member to avail himself of this protection. The present participation under the group plan amounts to only 48 per cent of the total membership, in spite of an actual net gain of 300 policyholders during 1940.

The membership is reminded that medical officers of the armed forces are not immune to damage actions for alleged acts of malpractice committed during their military service. It is necessary, therefore, that they continue their insurance while in the Army. However, it should be stated that they are not protected by their policy for the acts of their assistant or substitute in civil practice if said assistant or substitute is not individually insured. They may also be liable for the acts of their assistants or substitutes in their civil practices. Members entering the military service, therefore, have a two-fold incentive for keeping their malpractice insurance in force and also seeing that substitute is individually insured. It may be mentioned also that the policy of a principal under the group plan only protects him from actions growing out of the acts of an assistant if the latter is also a member of the State Society and is insured under the group plan.

The stability of the Yorkshire Indemnity Company, which underwrites the Society's group malpractice insurance, as a sound and dependable American company, is endorsed, and the cooperation of its officers and of Colonel Wanvig and his associates is appreciated.

I move the adoption of this portion of the report.

The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried.

Legal Counsel. Dr. CUNIFFE. This report is arbitrarily divided into three parts:

- 1 Actual handling of malpractice cases,
- 2 Counsel work with officers, committees, and individual members of the Society,
- 3 Legislative advice and activities.

It will be considered in that order.

Litigation.—The report again calls attention to the danger of unjustified criticism of the work of one physician by another as the frequent cause of an unjustified and unfounded malpractice suit. Where an opinion must be rendered of the poor result of treatment, that unfavorable opinion should never be given until one has ascertained all the facts and circumstances which entered into or affected the previous treatments.

The report calls attention to the hazard of a malpractice action to the practicing physician, not only to his peace of mind, ability to attend to his practice during the trial due to the delays which attend court work, but also the danger of an unfavorable and costly result. It should be borne in mind that the rights of the doctor are in the hands of lay jurors sometimes swayed by emotion rather than reason. This risk is increased somewhat by the presence of women

The motion was seconded

SPEAKER BAUER You have before you the recommendation of the reference committee, which carries with it the approval of the resolution as read. Is there any discussion on it?

DR HENRY B RICHARDSON, New York I should like to discuss this resolution. The members of the House have already accepted a report, part of which reads

"It has been our aim that the refugee physicians licensed to practice in this state and the foreign graduates licensed to practice in the state be treated on a basis of equality with the American doctor before the law in regard to commissions and in regard to military service "

A little below there is another sentence to that same effect

In listening carefully to this resolution, although the word "refugee" is carefully avoided, the burden of the resolution is to reduce acceptance of doctors from any medical schools outside of the United States and Canada who have not already been licensed

If the recommendation of the committee of reference is adopted, then on April 28 there comes about a change. Those individuals previously accepted for licensure become logically not fit to be licensed, and those who might be licensed later on after this date likewise become not fit to be licensed on a certain date

The effect of the resolution is for this House to reverse itself with respect to a report that has already been accepted on the same day

The number of doctors available per number of population has been mentioned. The fact that has not been mentioned is that we are in a state of preparedness, and that the number of doctors available for civilian work per unit of population is diminishing rapidly, and will diminish with much greater rapidity, to say nothing of the thousand physicians whom it is planned to send to Europe

CHORUS Nol Nol

DR RICHARDSON It appears to me that the Society faces a shortage of physicians and not a surplus, that they are putting themselves in the position of depriving the public of medical help that they sorely need

It seems to me that not only should the Society not reverse itself on any one day, but it should not put itself in the position of reversing itself in the near future

SPEAKER BAUER Is there any further discussion on this report?

DR GEORGE A BURGIN, Herkimer The Herkimer County Medical Society is heartily in favor of something of this kind. We feel that the resolution as suggested tonight is about four years too late. About four years ago we introduced a resolution, which was rejected, along the same line, with the idea of demanding that graduates from foreign schools or refugees coming here should fulfill the same obligations before getting a license that an American doctor might be required to fulfill in going to another country.

You may not be aware of the fact that in England, for instance, no matter where you are from and what your credentials may be, before being given a license you must spend at least one year in one of their medical schools before taking your state board. We feel that this should be

passed, and we are only sorry that it has been delayed so long (Applause)

The question was called for, and the motion was put to a vote, and was carried.

76 Report of Reference Committee on New Business B—Licensure—Requirement Full Citizenship (Section 15)

DR PETER J DiNATALE, Genesee On the resolution presented by the Medical Society of the County of Erie reading

"WHEREAS, it has been the custom of the Education Department of the State of New York to grant medical licenses to foreign physicians, and

"WHEREAS, this practice has not been to the best interests to the general public and also to the young people in this country who have studied in our medical schools, therefore be it

"Resolved, that the Medical Society of the County of Erie go on record as being in favor of requiring full citizenship as a prerequisite for the obtaining of a medical license to practice in the State of New York,"

Your reference committee recommends that this resolution be not approved because it is in part a contradiction of the resolution that you have just passed, and because it has been learned by your committee that attempts by our Legislative Committee to have such laws enacted have been shown to be impractical at present

I move the adoption of the report of the reference committee

The motion was seconded, and as there was no discussion, the motion was put to a vote, and was carried

77 Report of Reference Committee on the Report of the Council—Part VII—Legislation, and Malpractice Defense and Insurance, and Report of Legal Counsel

Legislation (Section 9) DR EDWARD R. CONNIFFE Your reference committee begs to express approval of the activities of the Committee on Legislation during the past session of the State Legislature and during the year

Your committee approves of the regular, special bulletins and comment sheets issued by the committee and the distribution thereof to all the component county societies

In this connection your committee approves that protest or approval comments be distributed to all members of the component societies after approval of such action and comment by the Committee on Legislation. This activity on the part of the component societies would serve to stimulate interest of our indifferent membership

Your committee commends the Committee on Legislation for its fruitful activities in combating the Wagner Health Insurance Bill and the Chiropractic Bill and also its efforts to protect and maintain our high, ethical standards in their opposition to the Quinn Bill which would have lowered the existing confidential relation between physician and patient. This latter bill, in spite of our opposition, was passed by the legislature, but was fortunately vetoed by the Governor

Law introduced into the Senate as Bill No 1195 has passed both the Senate and Assembly and is now awaiting the Governor's signature, any comments at this time on the amendment are academic

However, the amendment as presented in the report of the Council received complete review by your reference committee After consultation with a member of the Medical Grievance Committee of the Department of Education, we believe that some of the provisions in the amendments will improve the efficiency of the Medical Grievance Committee Undoubtedly, the provision in the amendment requiring that two-thirds of the members of the Medical Grievance Committee constitutes a quorum will curtail the number of fruitless meetings of the committee Your reference committee feels that the appointment of one member of the committee as a subcommittee to take testimony, will speed up the number of hearings and decrease the number of pending cases Your reference committee approves particularly the amendment which makes all cases come at least before a subcommittee for determination of trial necessity Your committee feels that the requirement that one of the majority for a decision of guilt be a member of the respondent's school of practice, will not be detrimental to the efficiency of this committee

I move the adoption of the reference committee's report

The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried

SPEAKER BAUER I recognize Dr Master-son, Chairman of the Reference Committee on New Business C However, for the information of the Chair, has anyone any further resolutions to introduce? If so, I will give you an opportunity as soon as we finish Dr Masterson's report to get them in tonight

79 Report of Reference Committee on New Business C—Leaves of Absence for Officers in Military Service (Sections 28, 66)

DR. JOHN J MASTERSON, Kings This is on the resolution presented by Dr Theodore West, of Westchester

"WHEREAS, many officers of this Society and of its District Branches are also officers in the Medical Reserve of the armed forces of the United States, and

"WHEREAS, such officers, when called to active duty, may, by reason of distance or the press of military work, be unable to function properly as officers of this Society or its District Branches, and

"WHEREAS, there is no provision in the present Bylaws of this Society to cover such an emergency, therefore be it

"Resolved, that any officer of the Medical Society of the State of New York or its District Branches who is called into active service with the armed forces of the United States may, upon application to the Council, be granted leave of absence during his period of active service, and be it further

"Resolved, that during such absence his duties shall be delegated as the Council may direct except where such delegation is already provided in the Bylaws"

After consultation with the Counsel of the Society we disapprove of this resolution for the following reasons

The Bylaws under Roberts' Rules of Order cannot be amended, changed or suspended by unanimous consent or by any consent except as they relate to procedural matters

The question under consideration does not relate to a procedural matter, hence we do not find any assistance from the unanimous consent

So far as the election of officers, Chapter 7, Section 11, of the Bylaws provides as follows

"The second vice-president, the assistant secretary, the assistant treasurer, the vice-speaker will serve as the first vice-president, the secretary, the treasurer, the speaker respectively whenever these senior officers are incapacitated for service by mandatory absence."

We can construe service in the Medical Reserve to the armed forces or Public Health Service of the United States as "mandatory absence" within the meaning of the above quoted Bylaws

So with the President under Chapter 7, Section 2, of the Bylaws

"The president-elect is to perform the duties of the president in the absence of the president In the event of the president's death, resignation, removal, incapacity or refusal to act, the president-elect shall succeed him."

Thus, we find that under the Bylaws the officers above enumerated do not succeed to the senior office, but merely act in their absence

The Bylaws do not provide for any other officer acting in the absence of another Hence, there is no provision which can legally take care of that situation in the event that such an officer should be a member of the Army or Navy forces

There is no provision in the Bylaws to take care of any officer of a district branch who may be called into active service in the armed forces of the United States or the Public Health Service of the United States

With the exception of the officers above enumerated, it will be necessary for any of the other officers when called into military service to resign if they find themselves unable by reason thereof to fulfill the duties of their office In that event the vacancy must be temporarily filled in accordance with the provision of the Bylaws (Chapter 4, Section 6)

We move the disapproval of the resolution

SPEAKER BAUER I think the motion is unnecessary It has been brought out that it is illegal, which was the previous ruling of the chairman, and I do not think it needs a vote It is ruled out of order

80 Report of Reference Committee on New Business C—Health Programs in National Defense (Section 57)

DR. JOHN J MASTERSON, Kings On the resolution introduced by Dr Samuel J Kopezky, of New York, reading

"WHEREAS, from many quarters measures which involve medical care of the public are being proposed in the interest and under the banner of the National Defense Program, and

jurors, also jurors out of work and on relief. It was necessary for a county of this state to call attention to the enormous and sometimes unmerited judgment resulting from juries composed in a great measure from people on relief. A modified method of the selection of jurors was necessary by the clerk of the county to correct this condition. However, it must hold to some extent during our present economic situation.

This tendency to unjust criticism should be actively attacked in all communities. It offers the most effective and sometimes only way in which unfounded and unjust claims can be discouraged and needless malpractice suits prevented.

The plea for insurance by more members is heartily approved. No one can afford to be without insurance protection at the present time. Last year 35 suits were prosecuted against doctors not insured by either the group or private insurance companies. No necessity for this warning should exist. A more active campaign for insured members should be undertaken.

We learn from this report that there were 131 cases for malpractice instituted during the last year as against 170 the previous twelve months. There were 145 disposed of as against 191 at the previous reporting, 103 were terminated in favor of the physicians. Forty of these cases were settled. Two cases resulted in judgment for the plaintiff as opposed to three in the previous year.

No fixed rule can be made as each case must be judged on its merits. Some must be settled, especially where there is negligence or error in practice. These settled cases are recorded in court as discontinued and no injury is done to the physician, and it is only practiced when an unfavorable result is expected.

The members of the Society may very easily pass over the work of counsel with a mere consideration of the department handling litigation. A great amount of work, however, is done which has no relation to the courts. It can be somewhat appreciated from a study of the report which lists thirty different subjects requesting advice and counsel. This was given orally, over the telephone, and in writing. These questions show the great diversity of the work of this office. Some are inquiries concerning ethical procedures. The counsel is primarily one to advise about matters of law. The elemental force of ethics is derived from the principles of ethics of the American Medical Association. Therefore, we believe that the counsel should be relieved of this work unless it is a question of law. The committee urges the Council to consider an amendment to our constitution setting up a body for the interpretation of medical ethics, to which committee questions could properly be addressed.

Again, among the many duties of this office is the advice given and consultations held with the many committees. Proposed amendments to our constitution, interpretation of the Bylaws, not alone of our State Society, but also many of its component societies, demand his attention. The drawing of commercial contracts with exhibitors and between officers and the Society are done by this office. These activities, together with the advice about legislation and the various

articles contributed to our JOURNAL, make a busy department which works during the entire year.

The committee extends its commendation for the excellent work of the department and the completeness of the annual report to our counsel and also to his able associates, Mr. Martin and Mr. Clearwater.

I move the adoption of this report.

The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried.

DR. CUNIFFE. Now I move the adoption of the report of the reference committee as a whole.

The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried.

78 Report of Reference Committee on Report of the Council—Part X

Memorial to Dr. Guy S. Carpenter. Dr. NORMAN S. MOORE, *Tompkins*. Your reference committee believes that the Council's Memorial to Dr. Guy S. Carpenter, of Waverly, New York, is a fitting expression of gratitude for the life of service which Dr. Carpenter unselfishly gave to this Society.

Election of Councilor. We believe that the Council acted wisely in electing Dr. Floyd Winslow, of Rochester, to fill the vacancy on the Council created by the death of Dr. Carpenter.

Nominations. We endorse as a wise choice the nomination by the Council of Dr. Peter Irving to succeed Dr. Nathan Van Effen as a member of the Nurse Advisory Council.

Likewise, your reference committee approves the nomination of Dr. Terry M. Townsend as successor to Dr. Orrin S. Wightman as a member of the Committee on Grievance of the State Department of Education.

Amendment to the Nurse Practice Act. Your reference committee approves the Council's decision to recommend the retention in the Nurse Practice Act of the requirement of endorsement by two physicians, members of a county medical society.

Annual Meetings. We approve the Council's appointment of Dr. J. Sidney Ritter, of New York, as secretary of the Section on Urology to fill the vacancy of that office created by the death of Lisle B. Kingery, M.D.

The creation of a new session of the State Society on the *History of Medicine*, is approved, and your committee is of the opinion that the new session will be an added interest to our scientific assembly.

The establishment of a round-table conference on Tumor Clinics to be held during the present Scientific Session is an example of the cooperation between the Council and the Committee on Scientific Programs. Such cooperation enhances the educational value of our annual meetings and your reference committee is favorable to this attitude on the part of the Council.

Delegates to Vermont State Medical Society. Your reference committee feels our Society was fortunate in having both the delegate and alternate to the Vermont State Medical Society represent us at the annual meeting in Vermont.

Amendments to the State Education Law. Because the amendment to the State Education

in the case of Dr Cottis, for two years, and in the case of Dr Rooney, for one year

83 Elections

SPEAKER BAUER According to the Bylaws the first order of business on the last session of the House of Delegates is the election of officers

TELLERS

SPEAKER BAUER The Chair will appoint the following as tellers

A A Gartner, *Erie*, Chairman
William A MacVay, *Monroe*
Frederic W Holcomb, *Ulster*
Madge C L McGunness, *New York*
Elliot T Bush, *Chemung*

ROLL CALL

SPEAKER BAUER As there is a quorum present, and as the tellers have already been announced, we will now proceed with the election

ELECTION OF OFFICERS, TRUSTEES, AND COUNCILORS

The following officers were elected President, Samuel J Kopetzky, *New York*, President-Elect and First Vice-President, George W Cottis, *Jamestown*, Second Vice-President, William A Krieger, *Poughkeepsie*, Secretary, Peter Irving, *New York*, Assistant Secretary, Edward C Podvin, *Bronx*, Treasurer, Kirby Dwight, *New York*, Assistant Treasurer,

"WHEREAS, the Medical Society of the State of New York, heartily favors the National Defense Program and has placed all its facilities at the disposition of the governments, State and Federal, in the furtherance of this Defense Program, and

"WHEREAS, it is a matter of fixed policy of the Medical Society of the State of New York to safeguard the modes of medical practice which have given the communities of this state its present high level of health as an outstanding medical achievement involving as it does preventive, curative, and public health medical measures, and

"Therefore be it Resolved, that each and every proposition which is advanced from any quarter whatsoever which would integrate a medical service to the community shall be studied as to its adaption into the emergency program with every necessary protection as to its discontinuance when the present emergency shall have passed, and which shall be written into its procedures, and

"Be it further Resolved, that it is the expressed policy of the Medical Society of the State of New York that at their introduction the temporary nature of necessary health measures be stressed as they are developed and that no general program shall be approved coming under the terms of 'part of the Defense Program' which permanently would change the nature and mode of the present method of medical practice,"

your reference committee approves the resolution and recommends its adoption, and I so move.

The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried.

81 Report of Reference Committee on the Report of the Council—Part VI—Medical Relief (Section 64)

SPEAKER BAUER Dr Van Kleeck, we did not quite complete your report. We left it in abeyance.

DR LOUIS A. VAN KLEECK Yes, the tail end of it.

SPEAKER BAUER The part we did not act on was the final part of Dr Van Kleeck's report which had to do with the direct payment for medical care to recipients of certain categories of relief instead of to the doctor, because there were two resolutions on the same subject that had been referred to Dr DiNatale's reference committee. The House voted, when Dr DiNatale made his report on those two resolutions, to take no action, and in effect to allow the plan to have an opportunity to work for an experimental period, and in the meantime permit the Subcommittee on Medical Relief to collect data on it. The final part of your report was in a similar vein.

DR. VAN KLEECK Yes.

SPEAKER BAUER You have already acted on the two resolutions reported on by Dr DiNatale in the way that is suggested in Dr Van Kleeck's report. We must finish his reference committee's report, which is really reiterating what we have already done for the sake of the record. Therefore, I place before you Dr Van Kleeck's recommendation for the adoption of that part of his report, which is practically

identical with what you have already adopted in connection with Dr DiNatale's report on those two resolutions.

The question was called for, and the motion was put to a vote, and was unanimously carried.

DR. VAN KLEECK Now I move to adopt the report of the reference committee as a whole.

The motion was seconded, and as there was no discussion, it was put to a vote, and was carried.

SPEAKER BAUER Are there any other resolutions?

(There was no response.)

SPEAKER BAUER I think there are only three resolutions left in the hands of the reference committees, and all reports on the Council committees, President, Secretary, Board of Trustees, etc., have been taken care of, so there will be very little business to do tomorrow, other than these three resolutions and the election of officers.

We will stand adjourned until nine o'clock tomorrow morning.

The session recessed at 10 30 P. M.

Morning Session

Tuesday, April 29, 1941

The session convened at 9 30 A. M.

SPEAKER BAUER The House will be in order.

There were announcements regarding the annual dinner, a meeting of the Medical Advisory Committee of the Saratoga Springs Authority, and the Conference on Medical Relief.

82 Board of Trustees—Resignations

SPEAKER BAUER The Secretary has two communications to read.

SECRETARY IRVING The first is from Dr Cottis.

"Dr Peter Irving, Secretary, Medical Society of the State of New York.

Dear Doctor Irving,

"I hereby tender my resignation as Trustee of the Society to take effect immediately.

"Respectfully,

G. W. Cottis (Sgd)"

The second is a telegram from Dr James F. Rooney.

"I hereby tender my resignation as a member of the Board of Trustees to take effect immediately.

James F. Rooney (Sgd)"

SPEAKER BAUER As many of you know, Dr Rooney is in the military service at the present time and out of the state.

What action do you wish to take on these resignations?

DR. ARTHUR J. BEDELL, Albany I move they be accepted.

CHORUS With regret.

DR. BEDELL With regret.

The motion was seconded, and as there was no discussion, it was put to a vote, and was unanimously carried.

SPEAKER BAUER I declare there are now these two vacancies in the Board of Trustees.

"Section 2 Qualifications

"No person shall practice the healing art unless he shall first have complied with the following prerequisites

"First, he must pass an examination given by the Board of Regents in the Basic Science, namely, Anatomy, Physiology, Chemistry, Bacteriology, and Pathology, and upon passing such an examination shall receive a Certificate of Proficiency in the Basic Sciences, which shall not confer the right to practice the healing art, and

"Second, after receiving said Certificate of Proficiency, he must pursue other studies as established by law and appear before the Board of Choice of the Board of Regents for further examination, and after having satisfactorily passed such examination, and having fulfilled other requirements prescribed by law, he may be licensed to practice

"Section 3 Penalty

"Any person violating any provision or provisions of the foregoing Sections shall be guilty of a misdemeanor punishable by law!"

The Reference Committee on New Business A recommended disapproval of this resolution on the ground that thorough enforcement of the existing Medical Practice Act would adequately accomplish the end sought, and this recommendation was adopted.

The other resolutions, after reports made thereon by reference committees, were either disapproved, or no action was taken.

SPEAKER BAUER We will now consider the executive session dissolved, and go into open session

85 Report of Committee on Awards of Scientific Exhibits

DR. WILLIAM A. KRIEGER, *Dutchess* As Chairman of the Committee on Scientific Exhibits I wish to express my appreciation for cooperation received from Dr. Wertz, Dr. Noehren, Mr. George Hale of the Hale Decorators, Inc., and the Hotel Management

The exhibits numbered 38 with 64 individuals participating Motion pictures consisted of 19 films

I also wish to express my thanks and appreciation to the Committee on Awards for their excellent work and judgment The Awards are as follows

RESEARCH

First

Ernest Witebsky, M D
Philip Weis
Anne Heide

Department of Pathology and Bacteriology
University of Buffalo, School of Medicine
Buffalo General Hospital
Buffalo

Laboratory Diagnosis of Trichinosis

Physical Findings in Bronchoscopy in Relation to Collapse Therapy of the Lung

SPEAKER BAUER Thank you, Dr. Krieger! (Applause)

86 Presentation of the Incoming President-Elect, Dr. George W. Cottis, to the House

SPEAKER BAUER Dr. Booth, would you consider yourself a committee of one to escort the new president-elect of the Society, Dr. Cottis to the platform?

Dr. Arthur W. Booth escorted President-Elect Cottis to the platform amid applause.

SPEAKER BAUER Dr. Cottis, I am very proud to be the first to congratulate you officially on your election. We all feel it is well deserved, and we know that the Society is very lucky in having you as its president-elect. Won't you say a few words to the House?

PRESIDENT-ELECT COTTIS Mr. Speaker and Fellow Members of the House of Delegates, I have nothing to say except that I realize the responsibility of this office which you have imposed upon me—I think "imposed" is the correct word. I accept it thankfully and humbly. I have watched the work of the presidents of this Society for thirty-five years. I attended the reunion meeting when the old State Society and the State Association buried the hatchet and became one unified professional organization. I have been intensely interested in the progress of Organized Medicine from that time to this, and that is why I realize the responsibilities imposed upon the officers of this Society. My only hope is that as a result of my years of observation of the way in which the past-presidents have devoted their time and their energy to this work I may profit enough by that observation to justify your choice.

I thank you! (Applause)

SPEAKER BAUER Thank you!

87 Notice of Intention to Amend Constitution and Bylaws

ASSISTANT SECRETARY POWIN I desire to give notice of a proposal to amend Article IV of the Constitution in regard to the Council, which now reads

"There shall be a Council composed of the President, the President-Elect, the immediate Past-President, the Secretary, the Treasurer,

James R. Reuling, Jr., *Bayside*, Speaker, Louis H. Bauer, *Hempstead*, and Vice-Speaker, William Hale, *Utica*

The following Trustees were elected George W. Kosmak, *New York*, for a five-year term terminating 1946, Edward R. Cunneiff, *Bronx*, for a two-year term terminating 1943, and William A. Groat, *Syracuse*, for a one-year term terminating 1942

The following Councilors were elected for a three-year term terminating 1944 Floyd S. Winslow, *Rochester*, Clarence G. Bandler, *New York*, and Harry Aranow, *Bronx*

ELECTION OF A MA DELEGATES

The following were elected 1942-1943 Delegates Louis H. Bauer, *Hempstead*, James M. Flynn, *Rochester*, George W. Kosmak, *New York*, Thomas A. McGoldrick, *Brooklyn*, Samuel J. Kopetzky, *New York*, John J. Master-son, *Brooklyn*, John T. Donovan, *Buffalo*, Frederic E. Sondern, *New York*, and Walter W. Mott, *White Plains*

The following were elected 1942-1943 Alternate Delegates William A. Krueger, *Poughkeepsie*, G. Scott Towne, *Saratoga Springs*, John L. Edwards, *Hudson*, John D. Carroll, *Troy*, Leo F. Schiff, *Plattsburg*, Alfred M. Hellman, *New York*, James N. Dobbins, *Long Island City*, Laurence D. Redway, *Ossining*, and Moses H. Krakow, *Bronx*

ELECTION OF RETIRED MEMBERS

The following members were elected to Retired Membership

Fred D. Andrew, *Rochester*, Annetta Barber, *Glens Falls*, Sherman Bates, *Richmond Hill*, Joseph Baum, *Far Rockaway*, Frank P. Bayliss, *Syracuse*, George H. Bell, *New York*, Clarence H. Bonnell, *Rye*, Samuel S. Brown, *Brooklyn*, Arthur H. Brownell, *Oneonta*, Alice Gates Bugbee, *White Plains*, Myron E. Carmer, *Lyons*, Howard D. Chapman, *Auburn*, Charles H. Chetwood, *New York*, Martin Cohen, *New York*, William J. Cranston, *Kingston*, Stanton Curry, *Peekskill*, Joseph Davidson, *New York*, George E. Davis, *New York*, Henry P. de Forest, *New York*, Fanny Dembo, *New York*, Roger Dexter, *Northport*, Frank L. Eastman, *Kingston*, David Felberbaum, *Miami Beach, Florida*, Hermann Fischer, *New York*, Philip J. Geathner, *Brooklyn*, Samuel Lee Gifford, *Whitesboro*, H. DuBois Goetchius, *New York*, Elias B. Guile, *Utica*, August Haasler, *Brooklyn*, Frederic C. Hargrave, *Pasadena, California*, Herman E. Hayd, *Buffalo*, Henry P. Hirsch, *New York*, Gustav A. Hitzel, *Buffalo*, James E. Holden, *Collins*, William Jacobsohn, *New York*, Smith Ely Jelliffe, *New York*, John Francis Kent, *Brooklyn*, Florence M. Loughton, *New York*, Theodore A. Lehmann, *Long Island City*, John Lennon, *New York*, Percy E. D. Malcolm, *New York*, Alexander Mark, *Elmira*, Herbert W. Matthews, *Penn Yan*, Fergus J. McDonough, *Brooklyn*, Marcus Neustaedter, *New York*, John W. Parrish, *Brooklyn*, M. L. Pinco, *San Diego, California*, Paul F. Pyburn, *Brooklyn*, Daniel L. Rogers, *Bolton Landing*, Chauncey A. Rood, *Brocton*, Jacob C. Rosenbluth, *New York*, E. Wood Ruggles, *Rochester*, Armand J. Salmon, *Brooklyn*, John J. Sheehy, *Garrison*, Herman B. Sheffield, *New York*, William L. Sneed, *New York*, Bernard Sour, *New York*,

Florence I. Staunton, *Peekskill*, Walter Whitcomb Strang, *New York*, Willard H. Sweet, *Peekskill*, Robert H. Tedford, *Albany*, Carl Theobald, *New York*, Belle Thomas, *Tampa, Florida*, Louis Van Hoesen, *Hudson*, John E. Virden, *Bronx*, Henry Wallace, *New York*, James Peter Warbasse, *Brooklyn*, August W. F. Westhoff, *Richmond Hill*, Julius Wolff, *New York*, and Victor L. Zimmermann, *Brooklyn*

84 Executive Session

DR. JOHN J. MASTERSON, *Kings* In view of the extreme importance of the resolutions to be considered this morning, I move that we go into executive session

DR. GEORGE W. KOSMAK I second that motion

There being no discussion, the motion was put to a vote, and was unanimously carried.

SPEAKER BAUER The House is going into executive session Will you check with your noble assistants to make sure that only members are present, Colonel Wentworth? The Chair will assume there will be no objection on the part of the House to the same exceptions being made as were made yesterday in so far as permitting those who are not members of the House to remain for the executive session Hearing no objection, the same exceptions will be made today as were made yesterday

COLONEL EDWARD T. WENTWORTH, *Monroe* The House has been cleared

(The House then went into Executive Session, receiving reports of reference committees on certain resolutions)

The following resolution submitted for Livingston County by Dr. Charles Guillo (*Section 53*) was considered

"WHEREAS, there are people in the State of New York practicing the healing art without having adequate knowledge of the human body, and

"WHEREAS, experience has shown that it is most difficult and often futile to effectively prosecute these people even when they have violated the Medical Practice Act, and

"WHEREAS, it is the duty of Organized Medicine to promulgate medical information and prevent fraudulent and inferior medical service to our people, now, therefore be it

"Resolved, that the House of Delegates of the New York State Medical Society hereby authorizes and directs the President of the New York State Medical Society to present to the Legislature of the State of New York a suitable bill to correct this condition and that such bill shall provide substantially as follows

"Section 1 Definitions, as used in this Article

"The practice of the Healing Art is defined as follows

"A person practices the healing art within the meaning of this article who holds himself out as being able to diagnose, treat, operate, or prescribe for any disease, pain, injury, deficiency, deformity, or physical condition of the human body, and who shall either offer or undertake by any means or method to diagnose, treat, operate or prescribe for any disease, pain, injury, deficiency, deformity, or physical condition of the same

Public Health News

The Tuberculosis "Must Go" Program

AT THE Annual Conference of State and Local Committees on Tuberculosis and Public Health of the State Charities Aid Association (held at the Hotel Commodore in New York City) the morning of May 21 was devoted to the following program

The First Year of the Program for the Substantial Eradication of Tuberculosis in Upstate New York by 1960—Progress and Next Steps

- 1 From the Point of View of Official Agencies
 - (a) "With Respect to Examination of Family Contacts," JAMES M. BLAKE, M.D., superintendent, Schenectady County Tuberculosis Hospital
 - (b) "With Respect to the Services of a Supervising Nurse," MISS MARION SHEAHAN, R.N., director, Public Health Nursing, State Health Department
 - (c) "With Respect to the Value of Tuberculosis Case and Contact Rosters," S. E. SIMPSON, M.D., superintendent, Jefferson County Sanatorium
 - (d) "With Respect to Clinic Expansion, Location, Housing, Equipment and Personnel," EDWARD X. MIKOL, M.D., Tuberculosis Division, State Health Department
- 2 From the Point of View of Nonofficial Agencies
 - (a) "With Respect to Tuberculosis Case-Finding by Practicing Physicians," PETER IRVING, M.D., secretary, Medical Society of the State of New York
 - (b) "With Respect to the Services of the State and Local Tuberculosis and Health Association," GEORGE J. NELLBACH, executive secretary, State Committee
- 3 "How It All Looks to Me at this Stage of the Undertaking," EDWARD S. GODFREY, JR., M.D., state health commissioner
ROBERT E. PLUNKETT, M.D., general superintendent, Tuberculosis Hospitals
Presiding DONALD B. ARMSTRONG, M.D., third vice-president, Metropolitan Life Insurance Company, member, State Executive Committee

The following address was made by Dr. Peter Irving, secretary of the Medical Society of the State of New York.

Case-Finding by Practicing Physicians

THIS new program will, I expect, impress all physicians in active practice in this state as a definite call to bestir themselves more effectively and at the same time more widely in the field of case-finding in tuberculosis. Throughout this century they have felt the obligation to their patients and to the public for early diagnosis and routing of cases to proper care. Now, as I see it, they will be able and glad to do more than they

have hitherto found it possible to accomplish toward these ends.

First, they will feel impelled to follow up the cases they find, into the families concerned, with uninhibited persuasion that family contacts be examined and x-rayed.

Then, they will be free to reach out in a newer fashion—a double fashion. First, they can seek from the tubercular patients and their families the names of individuals with whom the patients have come into close contact outside the home. These can be reported to the health officials together with names of offices where the patients have worked. The doctors can also do their best to get the patients or their families to pass on the suggestion that all these contacts would do well to seek examination and x-ray.

In this freer way, practicing physicians can step up the tempo of case-finding. They will, however, find problems as they go along. Particularly will the contact outside—and even inside the home—be reluctant to be examined and x-rayed. They can be expected to raise special objections to costs they consider unnecessary. Where funds are low—and the bulk of tuberculosis cases are found in the lower income groups—the objection may rest on real inability to pay. For these reasons it would seem an essential factor that all deterrents to examination and x-ray be in some way removed. The practicing physician meets a specific problem in the cost of x-ray, which flows primarily from the expense of equipment. The establishment of a principle that x-ray service in the Tuberculosis Control Program be made available to all without direct cost to the patients, to be paid for out of public funds, would result in the practicing physician's task being much more surely and widely successful.

The Council of the Medical Society of the State of New York has been studying these problems carefully for several months. On May 15, 1941, it placed on its records twelve "Suggestions Regarding the Tuberculosis Program." I can best give you its position by reading these—with comment.

1 The responsibility for communicable disease control rests largely with government health officials.

2 This responsibility carries with it the necessity of employing and advocating measures known or thought to be effective in disease control.

These two statements recognize government responsibility for initiation of control measures and, by implication the obligation of practicing physicians to help.

3 Such measures must be reasonable, without causing hardship, and at a cost which will not act as a deterrent. If the cost becomes relatively great, society must find a way.

the Speaker, and nine other members elected by the House of Delegates."

The proposed amendment is to be inserted after the word "speaker," "the Chairman of the Board of Trustees," so that as amended it will read

"the Speaker, the Chairman of the Board of Trustees and nine other members elected by the House of Delegates"

SPEAKER BAUER This is a notice of intention to amend the Constitution, which will be on the table in the Secretary's hands until next year, when after being published it will come before you for consideration

We will have the report of the Board of Tellers, but first is there any other business to come before the meeting?

(There was no response)

88 Presentation of Past-President Dr Allan A. Jones to the House

SPEAKER BAUER It has been brought to my attention that the oldest past-president of this Society, Dr Allan A. Jones, has just come into the House I think we should have Dr Jones stand

The delegates arose and applauded

PAST-PRESIDENT ALLAN A. JONES I am sure this is a very unexpected welcome on your part, and I appreciate it very much I have watched the proceedings of the Society for many years, and because of such watching I have come to know of what you have been able to accomplish I wish you the best of luck (Applause)

89 Vote of Thanks to the Speaker

DR. GEORGE W. KOSMAK, New York Mr Speaker, the hour has arrived when it may be appropriate to throw a few bouquets, and in order to save embarrassment to the recipient of the bouquets I want to throw I am going to ask the Vice-Speaker to act in your place for a moment, because I want to introduce a motion expressing the sense of the House in the excellent presiding qualities of our Speaker, the courtesy with which he has received the various men who spoke, and in general all the good things that are to be expected from a recipient of this office

I put that in the form of a motion, and I would like to have it put on the record (Applause)

DR. ARTHUR J. BEDELL, Albany I second that motion

The motion was carried by the delegates arising and applauding

SPEAKER BAUER I thank you very much, and I hope you will still feel the same way next year

90 Vote of Thanks to the Committee on Arrangements and Erie County Medical Society

SPEAKER BAUER I think it would be very much in order if someone would make a motion extending the thanks of the House to the Committee on Arrangements and all those who have worked so hard to make this meeting a success

DR. ALFRED M. HELLMAN, New York I should like to make such a motion and include our thanks to the Erie County Medical Society

SPEAKER BAUER I intended to include them in my suggestion. I am sure that does not need any discussion Again, I think we should take a rising vote

The motion was carried by all delegates present arising and applauding

SPEAKER BAUER Has anyone else anything to bring before the House?

(There was no response)

SPEAKER BAUER I remind you again of the dinner tonight, the ladies' hobby show which you are invited to see, the Council meeting at four, and the trustees' meeting at 4 30 this afternoon in the Erie County Medical Society's rooms on the eighteenth floor

91 Vote of Thanks to Chairman of Scientific Committee

DR. THOMAS A. MCGOLDRICK, Kings Mr Speaker, in the distribution of the bouquets at this time it seems especially fitting that the Chairman of the Scientific Committee, Dr Albert F. R. Andresen, on whom has rested the responsibility of the program for the day, and who according to the records deserves full credit and praise for this splendid program, should also receive our praise, which I feel he is entitled to I so move

The motion was seconded, and was carried by the delegates applauding

SPEAKER BAUER All committees having reported, there being no further business to come before this House of Delegates, I declare the 135th Session of the House of Delegates of the Medical Society of the State of New York adjourned sine die

(The session adjourned at 12 30 o'clock, noon)

SCIENCE WINNING THE FIGHT ON CANCER

An increase of nearly 30 per cent in fifteen years in cures of breast cancer was reported on March 30 by Dr Frank E. Adair of Memorial Hospital, chairman of the executive committee, American Society for the Control of Cancer

The increase, according to Dr Adair, is the result of the educational campaign by the society and its Women's Field Army on the importance of early diagnosis of cancer through periodic physical examinations and the avoidance of delay in reporting to a qualified physician any suspicious lump on the breast as soon as it is discovered

The data cover cases of women who have had no recurrence of the disease in five years

"Women have been told that cancer must be taken in its early stages to be cured, and they are taking advantage of this information," Dr Adair said "In 1920 the average delay in a breast case from the time a patient noticed a lump until she came to the hospital was eleven months and seven days In 1940 this lapse of time had been cut more than in half, to four months and four days

"In primary operable cancer of the breast in 1920 we secured 37 4 per cent five-year cures, in 1935, the latest year which we may use as a basis for calculating our five-year cure, we had raised the rate to 47 5 per cent, a gain of nearly 30 per cent in fifteen years"

Medical News

County News

Albany County

Dr George T Pack, of Cornell Medical College and Memorial Hospital, New York City, addressed the county society on May 28 on "Cancer of the Stomach."

Bronx County

The Bronx Gynecological and Obstetrical Society listened to the following program on May 26 Case Reports—(1) "Meigs Tumor," by Dr F A Wurzbach, Jr, and (2) "Repeated Bleeding During Pregnancy Due to Multiple Fibroids (2 Cases)," by Dr David Deutschman, Papers—(1) "Auto-Blood Injections in the Treatment of Functional Uterine Bleeding," by Dr Geza Weitzner, and (2) "Effects of Human Pregnancy Serum in Pregnant Animals," by Drs S S Rosenfeld, Bernard Lapan, and Dr Harry Baron.

Broome County

At the meeting of the county society on May 13, Dr James E Perkins, director, Division of Communicable Diseases, New York State Department of Health, presented the analysis of the Binghamton Pertussis study which was recently completed. Lantern slides were shown.

Radio speakers in May were Mrs John Robertson, Dr D G Dudley, and Dr M C Snyder

A joint meeting of the county society and the Binghamton Academy of Medicine, was held on May 26 in the Binghamton State Hospital assembly hall.

Colonel Harry A. Steckel, M.D., chairman of the committee on military mobilization of the American Psychiatric Association, spoke on "The Role of Psychiatry in the Present Military Emergency."

"Get their story," was the advice for a more thorough diagnosis of patients, by Dr Walter S Alvarez, Mayo Clinic surgeon and professor at the University of Minnesota, in an address before 325 Binghamton area physicians in Phelps Hall at City Hospital, on May 15

His talk, which climaxed Binghamton's observance of Hospital Day, was on "Puzzling Types of Abdominal Pain." The speaker called for more thorough diagnosis and "less dependency on the laboratory report." He decried the tendency to "skim over" the diagnosis—particularly on the part of "younger men"—and said that to obtain detailed stories of ailments from patients would be "invaluable" in planning action in cases where internal distress is evident

The first copy of the manual of the county society, which for many years was stored in the cornerstone of the old Binghamton Central High School building, has found its way into the Broome County Historical Section.

Printed in 1870, the volume is in a nearly perfect state of preservation, and reveals details of the first society, which was headed by Dr Daniel A. Wheeler. Binghamton was then Chenango Point

The pamphlet was taken from the cornerstone when the building was razed and was presented to Dr Blinn A. Buell in 1940, when he was head of the society

It contains the chronologic list of members from 1806 through 1870 and gives a schedule of fees that was something to behold in those days

Columbia County

Dr Willis W Lasher, of the Reconstruction Hospital, New York City, and formerly of Germantown, was guest speaker at the meeting of the county society at the Taconic Inn, Copake Falls, on May 13. He spoke on "Some Affections of the Knee Joint." Dr R. P. Harris presided

Errie County

At the meeting of the county society on May 27, Dr Critchlow reported that to date the Western New York Medical Plan, Inc., has paid 1,002 claims, and for the last quarter the amount will be over \$3,000

Dr Bauckus stated that he had been appointed to represent Erie County on a committee to meet with the Farm Security Administration. This latter organization will make loans to poor farm families which will enable them to subscribe for medical expense indemnity insurance. It was the opinion of the committee that the question should be brought before the organization of the Rural Physicians of Erie County. Mr Metzger of the Western New York Medical Plan and a representative of the Farm Security Administration were present at the meeting and the situation was thoroughly discussed. The rural physicians voted to go along with this plan of medical expense indemnity insurance, which is to be taken care of through the Western New York Medical Plan. Dr Bauckus recommended that inasmuch as the rural physicians organization has approved the plan and that the Society approved the Western New York Medical Plan, the county society approve it. It was moved, seconded, and carried that the society accept this recommendation.

The Buffalo Academy of Medicine will have its annual golf and field day at the Orchard Park Golf Club on Thursday, July 10, with dinner at 7 00 p m

Franklin County

The semi-annual meeting of the county society was held June 4, at the John Black Memorial Room, at Saranac Lake

Medical problems relating to the Selective Service system as affecting upper New York State were discussed by Col. Louis H. Gause, M.C., medical advisor, Selective Service, New York State Headquarters

Kings County

The following scientific program was given at the meeting of the county society on May 20 (a) "The Diagnosis and Treatment of Lesions of the Cranial Nerves," by Dr Walter E. Dandy

which is usually sharing cost through government taxation

The element of cost of new measures is here recognized—and that, if necessary, the burden may be spread by use of public funds. Now comes the estimate of the cost of the particular measure of present concern in

4 The per capita cost of x-ray examination for tuberculosis diagnosis is not a financial burden to some people, but to the *great majority* it is

5 X-ray examination is necessary as a part of the Tuberculosis Control Program and *must be made available*

6 X-ray examination necessitates expensive equipment and specially trained physicians

Now comes the most significant, practical adoption of a new and definite stand in

7 Patients who, in the opinion of the health officer or his representative, for various reasons (contacts, etc.) should have a thorough physical examination including x-ray, as a part of the Tuberculosis Control Program, should be rendered x-ray service without direct cost to the patients

I will not go into the definition of the term "a thorough physical examination" except to say that it must be sufficient to ensure a diagnosis. The stress here is on x-ray examinations at no cost to contacts. This suggestion goes on to set up safeguards by saying

All such examinations should be done only on the written order of the health officer or his representative, or the order of the family physician, and approved by the health officer, or his representative. The x-ray examinations are to be made only by physicians licensed to practice medicine in the State of New York

8 All x-ray examinations at tuberculosis hospitals and clinics should be done without direct cost to the patients

9 X-ray examinations, when ordered as a part of the Tuberculosis Control Program by the health officer and performed by a private physician, *should be paid for from public funds*

10 No patients, except in emergency, should be examined at tuberculosis hospitals and clinics without a written order from the health officer or his representative

These three statements relate to procedure. I would call your special attention to the provision for payment from public funds for x-rays of these contacts by private physicians. In other words, it should be recognized that the practicing roentgenologist has a place in the picture as well as the tuberculosis hospital and clinic

11 In order to prevent lack of service and to encourage active participation of local health units, part or all of the cost of x-ray examinations *should be borne through state aid*

This, again, is recognition of public responsibility

12 To avoid misunderstandings regarding interpretation of x-ray findings, techniques, and other matters, provision should be made for the establishment of an *Advisory Board on x-ray procedures*. Such a Board should be composed of radiologists, the majority of whom are in the private practice of medicine. The members of this Board *should be compensated by and function as a part of the State Department of Health*

This is a new idea based on the desire to integrate the work of public officials and practicing physicians to the end that the case-finding be more complete than it has been before

If these suggestions can be put into operation, it is the belief of the Council that the practicing physicians of the state will do their full part. The Medical Society of the State of New York will do everything to encourage their success

PITFALLS OF HOME DIATHERMY

"Diathermy for use in the home has been extravagantly promoted by various agencies, the *Journal of the American Medical Association* for April 5 declares in an editorial

"The *Journal* has emphasized repeatedly that any kind of self treatment without scientific diagnosis may be hazardous because it permits neglect of serious conditions that may require professional attention. In several cities, firms have come into being practically overnight, advertised in the daily papers, broadcast over the radio, released high pressure salesmen to sell or rent their products, then they have suddenly disappeared, although in some instances the promoters have appeared in the same role in new firms which repeated this program. Some of these instruments promulgated to the public have been efficient, others have not! Apparatus for diathermy should have sufficient output to heat the tissues, since heat is the only therapy it provides for which critical evidence is available. If the instrument is efficient, it may be dangerous unless its use is supervised by a trained observer. If the machine is inefficient and of low power output, it will not heat the tissues and will be without therapeutic effect."

WHAT BECAME OF YOUR PRACTICE

If you are one of those who think that the medical "business" is not what it used to be, look over this list of medical services that are actually being rendered in Columbus

Orthopedics by osteopaths, chiropractors, and shoe stores

Surgery by osteopaths

Refraction by optometrists

Over-the-counter prescribing by druggists

Psychiatric advice by psychologists

Pathology by lay laboratories

Rupture reduction and treatment by rupture clinics and truss companies

Physical therapy by mechano-therapists and chiropractors

Agglutination tests for paternity by geneticists

Speech difficulties, with the use of x-ray, by a nonmedical clinic

Dietary advice by faddists

Weight reduction, colonic irrigations, treatment of colds, arthritis, etc., by bath houses

Self-prescription through patent medicine advertisements

The poachers don't seem to have missed much, have they?

—*Bulletin, Columbus Academy of Medicine*

Wayne County

The county society met on June 10 at the Newark Country Club, and listened to a lecture by Dr Nathan P Sears, professor of clinical gynecology at Syracuse University, on "Carcinoma of the Female Genitalia."

Westchester County

Dr Matthias Nicoll, Jr, aged 73, of Rye, who died on May 13, was State Commissioner of Health from 1923 to 1930.

Colonel Edward H Marsh, former county deputy health commissioner, talked on "A Doctor Looks at Mobilization" before forty members at a closed meeting of the White Plains Medical Society at Westchester Hills Golf Club, on May 13.

Wyoming County

Dr Willard L Chapin, of Perry, and Dr Valente, of Strykersville, both reserve officers in the medical corps, have been cited for deferment from Army duty at this time by the County Medical Defense Board, of which Dr Oliver T Ghent, of Warsaw, is chairman. The board is composed of members of the county society.

The reason in both instances is the belief that their departure from their communities would be contrary to public interest from the health standpoint.

In the case of Dr Valente, deferment is recommended because he is the only physician in his community and his departure would leave the village without medical service.

FAITH AND PILLS

Yesterday I heard of a remarkable young doctor who offended a patient by refusing to give her any medicine. He said he didn't know what was the matter with her, and he couldn't prescribe medicine without seeing some reason for it.

The grim honesty of that attitude is a rebuke to quacks, but it may not always be wise.

One bright Sunday morning, years ago, I rode downtown with a kindly old doctor who was both a scientist and a philosopher. We hadn't gone far when a lady pushing a baby carriage signaled the doctor to stop and asked him to examine her ailing infant.

Doc took the child on his knee and played with it for a minute or two and then began to write a prescription.

"Give this as directed," he said, "and if the baby isn't better by tomorrow morning, bring it to my office."

This seemed a miraculous diagnosis, and as we drove on I asked Doc what was wrong.

"Not a thing in the world," he answered cheerfully. "The medicine was to pacify the mother. It won't hurt the baby, and if there is anything wrong, it will develop by tomorrow morning so I can tell what it is. The mother thinks there's something wrong, and if I had done nothing for the baby, she would have taken it to another doctor."

The old-time medical doctor may have been short of learning, but he knew human nature.

The recent epidemic of doctor's autobiographies makes it clear that the old-timers, for all their scorn of faith cures, cured by faith without realizing it. Both the doctor and his patient believed in the curative value of medicine, and the doctor gave it generously—a different kind for each symptom. The "ease his pain and wash him out" theory worked all right, unless the patient had appendicitis, but the other dosings probably cured nobody.

How, then, were they cured? By nature, plus faith. People believed in their doctor and felt safe when he stepped inside the door. If he had given them flour pills, his service still would have been worth all he received, for he took away their fears and gave them the hope and confidence they needed to get well.

Modern doctors give little medicine. Doubtless they would feel like quacks if they gave flour pills when the patient's symptoms seemed to call for nothing more. But human nature has not changed. We still live by faith. And half the value of medical science will be gone when cures depend on medicine alone.—Robert Quillen, in *Foundation Inn Tribune*, quoted in *Clinical Medicine*.

F.A.C.S., Baltimore (b) "The Essential Systemic Nature of Acute Lupus Erythematosus and Other Generalized Diseases of the Skin," by Dr Paul Klemperer, Manhattan

The Brooklyn Thoracic Society met on May 16, with this program (1) "Bronchial Catheterization and Bronchography," by Dr Samuel A. Thompson, New York City, with the discussion by Drs Harry Meyersburg and Ralph Harloe, (2) "Artificial Pneumothorax in the Treatment of Pulmonary Tuberculosis" (sound motion picture), by Dr James S. Edlin, New York City, with a general discussion.

Monroe County

The president of the State Society, at Rochester, on May 29, urged the Federal Government to enlist in the national defense effort foreign physicians who have been driven from their homes to this country, as reported by the Associated Press.

Asserting that 9,000 medical officers will be needed during the next year, Dr Samuel J. Kopetzky, who also is medical director of Selective Service in New York City, told the county society in a prepared address "There are about 2,500 medical men of foreign extraction, driven by persecution from their native lands, who are located in various parts of this state. The authorities should survey their equipment and qualifications, and place them, too, at work in the defense program."

Pointing out that organized medicine has "pledged its facilities to the Federal Government in supplying the medical needs of the armed forces," Dr Kopetzky declared, "this united effort is no mere lip service, it is an actual contribution."

"We as doctors," he said, "must take the yardstick of quality of medical care, and measure every possible advance in the name of our national defense program, and see to it that however much necessity exists because of instant situations this shall not break down the employment of our constant yardstick."

"It should be our duty to so plan measures integrating community medical care in the defense program that they carry within themselves their discontinuance or dissolution when the present pertinent emergency shall have passed and become history."

Nassau County

Dr Charles W. Martin, of Woodmere, succeeded Dr Aaron L. Higgins, of Rockville Centre, as president of the county society on May 27, at a meeting at the Cathedral House, Garden City. Dr Martin was president-elect for the past year.

The annual election of officers resulted as follows: president-elect, Everett N. Whitcomb, Port Washington, vice-president, N. H. Robin, Hempstead, secretary-treasurer, E. Kenneth Horton, Rockville Centre, board of censors: William C. Atwell, Great Neck, John M. Galbraith, Glen Cove, Stephen F. Gerde, Freeport, A. M. Goldman, Rockville Centre, Charles Edwin Woods, Westbury Workmen's Compensation Board (2 years) Wright F. Lewis, Freeport, Ruel L. Alden, Hempstead, James L. Winemiller, Great Neck. Delegate to State Society (2 years) Louis A. Van Kleeck, Manhasset.

New York County

A testimonial dinner, sponsored by the county society, was given on June 12 at the Hotel Plaza, in honor of Dr Samuel J. Kopetzky, president of the State Society. Among the speakers was Col Arthur J. McDermott, director, Selective Service for New York.

Dr Arnold H. Knapp, of New York City, is the recipient this year of the Leslie Dana Gold Medal awarded annually for outstanding achievement in the prevention of blindness and the conservation of vision. The award is given on the recommendation of the Association for Research in Ophthalmology.

Dr Knapp is editor-in-chief of the *Archives of Ophthalmology* and professor emeritus of ophthalmology in the College of Physicians and Surgeons of Columbia University. He is also consultant to the Eye Institute of the Columbia Presbyterian Medical Center and is one of the three directors of the Knapp Foundation in Ophthalmology of Columbia University.

The conditions of the Leslie Dana Medal award set forth that it is made for "long meritorious service in the conservation of vision in the prevention and cure of diseases dangerous to eyesight, research and instruction in ophthalmology and allied subjects, social service for the control of eye diseases, and special discoveries in the domain of general science or medicine of exceptional importance in conservation of vision."

Oneida County

Dr Conway A. Frost, aged 74, of Utica, who died on May 10, was a past-president of the county society.

Queens County

A tentative program has been drawn up for a course in allergy to be given at the county society in October. Arrangements are being completed through the chairman of the State Society's Committee on Public Health and Education. It is requested that those interested communicate with the chairman of the Graduate Education Committee. Attendance will be gratis.

Schenectady County

The semi-annual meeting of the county society was held at the Mohawk Golf Club on June 5, with a luncheon at noon followed by golf, tennis, putting matches, and bridge.

The business meeting was held at 5:30 with a dinner following.

Dr D. Glen Smith and his all-doctor orchestra entertained after dinner. Dr Charles E. Wiedeman is president of the society.

Tioga County

The quarterly meeting of the county society was held on June 3, at the Green Lantern Inn, following dinner. Dr Charles J. V. Redding, of Owego, presided at the meeting, which was attended by sixteen members.

The speaker was Dr J. Zillhardt, of Johnson City, who spoke on "Blood Transfusions and Blood Banks." Dr Zillhardt is internist on the medical staff of the Endicott-Johnson Corporation.

shot wounds. Dependents will receive one-half of the full allowance for surgery and the full amounts for the benefits first listed.

Plan I costs subscribers \$1.40 and Plan II is offered for 80 cents a month for gainfully employed persons. The benefits are increasingly greater than offered by the new plan.

Harold C. Stephenson, managing director of the Hospital Plan and the Medical and Surgical Care Plan, said, in announcing Plan III, that it was the first of its type to be sponsored by physicians and offered at such a low price.

He explained that a husband and wife could enroll for 99 cents a month, while all children in a family, regardless of number, between the ages of 1 and 16 were covered for one payment of 39 cents a month.

Nonprofessional employees of the Methodist Hospital of Brooklyn, members of the State, County and Municipal Workers Union, C I O, are prepared to present demands to the hospital management, calling for union recognition, \$60 a month minimum pay, two weeks' paid vacation a year and two weeks' sick leave, and eight paid holidays a year, says the *Brooklyn Eagle*.

Dr. Chester A. Marshall, director of the hospital, has appealed against what he called an impending strike at the hospital, but David Allen, secretary-treasurer of the New York area of the union, has declared that no strike has been threatened or suggested.

The citizens of Bainbridge, Guilford, Masonville, Sidney, and Unadilla have approved a plan to join in erecting a hospital, the location not yet selected.

The estimated cost of the hospital building, which will contain thirty-seven beds, is from \$80,000 to \$100,000 and for the equipment which is needed in a modern hospital the cost is estimated to be from \$50,000 to \$60,000.

An increase in rates for county welfare cases at the Lockport City Hospital has been reported to the Board of Supervisors by Miss Nettie MacMillan, superintendent.

Where \$3.50 a day has been paid, the hospital managers have asked \$4.50 plus extras or \$5 a day flat rate. "Greatly increased cost of maintenance" was given as the reason for the request. The communication was referred to the welfare committee.

Ellis Hospital, Schenectady, has raised its room rates by 50 cents to obtain much-needed revenue.

The total loss sustained by Vassar Brothers Hospital as the result of free or less-than-cost care given county patients over a period of eighteen months from November 1, 1939, to April 30, 1941, has been announced as \$39,234.

Improvements

The cornerstone of the new million-dollar addition to the Roosevelt Hospital, New York City, was laid on May 21.

Plans to erect a new building for the Downtown Hospital and Pan-American Clinic, New York City, formerly known as Broad Street Hospital, are under consideration.

Ground was broken on May 28 for the new million-dollar, 375-bed building of St. Mary's Hospital at Bulls Head, Rochester.

Due to the increase in population in the Westchester and Parkchester areas of the Bronx, Westchester Square Hospital is erecting a four-story extension to the present building.

Illion Hospital contemplates a \$115,000 addition.

Seventeen two and three-story brick dwellings adjoining the Cumberland Hospital located in the center of the Fort Greene Housing Project in Brooklyn are to be demolished soon by WPA to clear the immediate area for future expansion of that institution, Major Irving V. A. Huie, New York City WPA administrator, announces. The work will be performed at the request of the New York City Housing Authority.

The Lee Memorial Hospital at Fulton is raising \$85,000 for expansion.

St. Francis Hospital, Poughkeepsie, is adding a new wing, with other enlargements and improvements.

The Brooks Hospital at Dunkirk plans an addition.

A movement is on for a \$50,000 addition to the Canastota Hospital.

OUR DICTATORS REVEALED

The dictators of organized medicine are the practitioners of medicine, every one of whom has a voice which will be heard when it expresses a

constructive thought, even though it express adverse criticism.—N. B. Van Etten, M.D., president of the A. M. A.

Hospital News

Hospitals Report Shortage of Drugs

SCARCITY of essential chemical and pharmaceutical supplies, attributed to diversion of the basic chemicals to industrial uses in the defense program, is reported by both private hospitals and the New York City Purchasing Office, Division of Chemical and Drug Purchases, says the *New York Times*. Smaller manufacturers of medicinal supplies reported that they were faced with shutdowns unless priority ratings of defense contractors, shifting basic chemicals from pharmaceutical to industrial uses were modified. Druggists, although still able to buy patent medicines with little difficulty, were finding it hard to purchase several crude drugs.

Manufacturers of basic chemicals said the situation was one for which they were unable to prepare. They had carefully built up systems allocating their available production among regular customers and, while this did not fully meet the needs of customers, no one was being forced to go without essential materials. This worked rather well, manufacturers said, until the priority rating system of the OPM went into effect. Under this system, any defense contractor may get a priority rating that requires his suppliers to fill the defense contractor's needs above those of all other customers, without regard even to prior commitments to regular customers.

Typical of the products affected by the defense log jam, producers said, was methanol and its product, formaldehyde. These are used extensively in the manufacture of pharmaceuticals and also are important in production of resins from which plastics are made, and the plastics are getting the priority ratings.

Zinc products used for medical purposes were increasingly hard to buy, according to makers of ointments and similar products. With all available zinc going into munitions and defense production, zinc oxide and zinc stearate production has been cut sharply.

In addition to the interruption of pharmaceutical supplies due to diversion of the chemicals to industrial uses in the defense program, both drugstores and hospitals have experienced a growing shortage of a number of imported products, notably botanicals, essential oils, and herbs. Codliver oil, normally imported from Norway, is hard to buy, and prices are nearly three times the prewar levels.

Interns "Gone with the Draft"

NEW YORK City hospitals will face a shortage of interns by next autumn as medical graduates are called to meet the increasing demands for medical officers in the Army, according to Dr Willard Cole Rappleye, commissioner of Hospitals, says the *New York Post*.

For 6,700 internships in hospitals of the country there are annually about 5,000 medical graduates, he explained, but the extra internships have been taken up until the present by second-term interns. These are young men who, having finished their internship in a smaller hospital, go

for a second internship for specialized training in large medical centers.

Now, with the Army calling for doctors, Dr Rappleye says, these second-term interns are being called to the service, leaving hospitals short-staffed.

Recent rulings of the Selective Service System allow medical students deferment until after their internship, but will prevent young doctors from taking more than one course of internship, as men of draft age are not eligible for second internships.

New York City will feel the shortage most acutely, for about one-sixth of all medical graduates of the country are taken into New York hospitals for their postgraduate training. About one-fifth of the nation's resident positions for doctors in hospitals are provided by local hospitals. There are between 1,600 and 1,700 internships in the local hospitals. Just how many young men will be available to fill these posts during the coming year is not yet known.

However, there is no danger of a shortage of practicing physicians. There are now twice as many physicians per unit of population in the United States as in any other country in the world.

Newsy Notes

MORRIS P. Tanner of the Children's Hospital, Buffalo, was elected president of the Hospital Association of New York State on May 22 at a meeting at the Hotel Pennsylvania, New York City. David Q. Hammond of Flower Hospital was elected first vice-president and Harold A. Grumm, of Buffalo, second vice-president. Austin J. Shoneke of New Rochelle Hospital was named treasurer.

• • •

An emergency plan for the medical defense of New York City, dividing the city into twelve zones and setting up a hospital as key center for each zone, is declared ready for functioning by Hospitals Commissioner Willard C. Rappleye.

Cooperating will be forty private hospitals, ready to send ambulances or evacuate patients, while crews of specially trained doctors and nurses will be on hand for swift first-aid treatment. In addition, 12,000 Sanitation Department employees are being mobilized by acting Commissioner John B. Morton.

• • •

A third plan offering benefits at a cost of 48 cents a month has been announced by the Medical and Surgical Care Plan, which cooperates with the Hospital Plan, Inc., of Utica.

Under the new plan the gainfully employed subscriber and all dependents will be entitled to an allowance of \$10 for anesthesia, \$5.00 toward x-rays, \$5.00 toward special laboratory, basal metabolism, or electrocardiograms, and, in addition, \$200 for each gainfully employed person toward a list of eighty-three surgical procedures that include fractures and the treatment of gun-

presence of the needle sooner than he did, the Court said in part

"The total length of time which elapsed between the operation, and giving plaintiff the information concerning the needle's presence, was six weeks. More than two of these were spent in the hospital and when she left it she was removed in an ambulance. Thereafter recovery seems to have been rapid, and within a little more than three weeks after she returned to her home, and within ten days after she first appears to have been able to go to defendant's office, he informed her fully concerning the facts and the necessity for removal. We cannot say as a matter of law that defendant should have informed her earlier, or that a jury would be justified in finding that he should have done so. He acted with reasonable promptness in view of all the circumstances and a verdict that it was negligent for him not to do so earlier, on the

evidence here presented, hardly could be sustained. The mere fact that plaintiff suffered pain from the needle during the period prior to its removal does not make the failure to remove it earlier negligent. In addition to the shortness of time, it must be remembered that her physical condition for at least ten days following the operation was serious, her tendency toward nervousness was high, and the location of the needle in the fatty tissue made danger of infection or movement to a zone of danger slight. In these circumstances there was no need for haste, and there may have been real need for delay sufficient to assure that excitement or psychological disturbance incident to the removal would not cause a relapse in the patient's physical recovery. In the light of these facts the evidence indicates that the delay was not negligent rather than the contrary."

Inquiries

YOUR counsel recently received the following inquiry

"Dear Mr Brosnan

"At one of our intern conferences the question came up. Is an intern, as an individual, liable to be sued for malpractice for any act performed while serving as an intern in the hospital? If sued, is he personally liable for any judgment obtained or is the hospital liable for a judgment obtained?"

Very truly yours,"

Your counsel's reply was as follows

"Dear Doctor

"I acknowledge receipt of your letter in which you ask certain questions which have arisen at one of your intern conferences

"Your first question is 'Is an intern as an individual liable to be sued for malpractice for any act performed while serving as an intern in the hospital?' There is no question but that an intern may be personally sued for malpractice in connection with the personal care by him of a patient while serving as an intern. In my experience, in certain instances, interns have in fact been named as party defendants in malpractice actions. They are responsible to patients personally treated by them under the same rules of law as would be physicians who are members of the attending staff of the hospital. Undoubtedly, the reason why interns are not more frequently sued is that attorneys realize that interns are rarely financially responsible

"Your second question is, 'If sued, is he personally liable for any judgment obtained, or is the hospital liable for any judgment obtained?' If a judgment is rendered against an intern in a malpractice action, which is a perfectly possible outcome of such an action, the judgment would be collectible from the intern personally. Unless the judgment were directly rendered against the hospital as a party defendant, it would not be responsible for the judgment. In other words, a hospital is under no legal obligation to indemnify an intern in the event

of a malpractice judgment rendered against him personally

"It should also be pointed out that in ordinary cases, when a hospital is directly sued on the theory that one of its interns committed malpractice in the care of a patient, a hospital is not ordinarily liable for the negligent acts of the intern, provided it has used due care in seeing that the intern was properly qualified to act as an intern, and further provided that the hospital did not delegate to the intern duties which were not properly within the scope of an intern's duty

Very truly yours,"

A recent inquiry addressed to your counsel was as follows

"Dear Mr Brosnan

"I would like to have your opinion on the following. *First* If I refer a patient to another doctor, am I responsible for the treatment or operation? *Second* If when on vacation, my telephone calls are referred to another doctor who is a clinical assistant, appointed by the Board of Trustees of a hospital and has no connection with me or my personal practice, financially or otherwise, would I be responsible for any acts of this doctor in connection with a case I have never seen?"

"For any service rendered by this doctor, collection is made by him direct as his own patient, in which I have no interest. Personally, I cannot see how I would be any more responsible than if you sent a client to another attorney

"Thanking you in advance I am,

Yours truly,"

Your counsel's reply was as follows

"As a general proposition the answer to both of the questions propounded in your letter is that you would not be responsible for the acts of the other physician, as in the eyes of the law you and the other doctor are independent contractors, each responsible for his own act but not for the act of the other

"To the general rule, however, there may be

Medicolegal

LORENZ J. BROSNAN, Esq.

Counsel, Medical Society of the State of New York

Liability of Surgeon in Needle Breaking Case

AN INTERESTING case was decided a short time ago in a nearby jurisdiction which involved the legal consequences of the breaking of a needle under circumstances that undoubtedly have arisen in numerous instances.*

On January 24 the plaintiff underwent a gall-bladder operation performed by Dr. S, the defendant in the case. After the operation she was taken to her room, and Dr. S concluded that her immediate postoperative condition was such that she required the administration of a saline and glucose solution by hypodermoclysis. He instructed an intern, Dr. P, who was associated with the hospital staff, to do the actual work of administering the solution. Dr. P proceeded to do so before the patient regained her consciousness from the anesthetic. He utilized equipment furnished by the hospital. It seems that the lights had been dimmed in the patient's room and were not brightened during the injection. The intern inserted one of the needles under the armpit into the right side of the patient's body and it broke off at the hub and left a segment two inches in length in the tissues.

The intern, Dr. P, examined the broken hub and found, as he testified on the trial, that it was rusty inside and, he felt, latently defective. He tried to retrieve the broken fragment himself and with the assistance of a Dr. M, whose position was that of resident surgeon. But such efforts were of no avail, so the operating surgeon, Dr. S, was summoned. It was the conclusion of Dr. S, after examination, to temporarily allow the needle to remain where it was.

The patient had certain complaints of pain in her side for the next six weeks at intervals, and on March 7 she was told by defendant about the needle. She sought the advice of another doctor and in two days she returned to Dr. S, who operated and extracted the needle. It was rusty when removed. After that the patient continued to seek medical care with reference to pains in her side.

The patient sued the surgeon, Dr. S, charging him with malpractice both in connection with the breaking of the needle in the first place, and in connection with the alleged failure to remove it promptly. Upon the trial the proof showed substantially the fact situation outlined above. There was no medical testimony that defendant's treatment was contrary to proper and accepted practice. The trial court directed the jury to return a verdict for the defendant on the following grounds: "(1) defendant was not responsible for the negligence of the intern, if he was negligent, since plaintiff failed to prove that Dr. P was in defendant's employ, (2) plaintiff had failed to prove that defendant's treatment after the needle had broken off in plaintiff's body was

not in accordance with the standard of physicians practicing in the district."

The plaintiff appealed, but the Appellate Court affirmed the judgment in favor of the doctor. In its opinion the Court said in part:

"There is authority for the view that an operating surgeon is liable for the negligence of hospital employees while actually assisting him in the operating room. But where employees of the hospital are negligent in carrying out the surgeon's instructions as to treatment after the operation, the overwhelming weight of authority holds that the surgeon is not liable in the absence of a showing that he was negligent in giving the instructions or selecting the persons to carry them out, that he was present and could have avoided the injury by exercising due care, or that his special contract relative to the negligent employee was such as to make the doctrine of *respondet superior* applicable. These cases clearly hold that the mere fact that the surgeon gives the instructions, or even specially designates the particular employee who is to carry out the instructions, does not give rise to a master-servant relationship. Part of the service furnished to the patient, and charged for by the hospital, is the assistance of nurses, interns, and attendants in caring for the patient after the operation, pursuant to instructions given by the operating surgeon. They perform the duty of their employer (the hospital) to the patient when they carry out the instructions of the doctor. Such evidence as there is on the point indicates that it was part of the normal duties of interns at E Hospital to give hypodermoclyses after operations. There is no suggestion that it is the sort of thing which the operating surgeon must do himself, that it is not customary to have interns do it, or that defendant expressly or impliedly contracted to perform it himself.

"It follows that defendant's giving instructions to the intern to administer a hypodermoclysis did not alter the master-servant relationship between the hospital and the intern, and did not create an employment contract or relation between defendant and the intern. The fact that defendant's instructions related to a 'medical measure' rather than to 'usual nursing measures' cannot in itself create an employment relation. It is not suggested that defendant was negligent in giving his instructions, or in assigning the duty to the intern, and, as we hold the doctrine of *respondet superior* is not applicable, we need not decide whether the intern, Dr. P, was negligent."

With reference to the contention that defendant had been negligent in not disclosing the

* *Hohenthal vs. Smith* 4 Neg. Cas. 1941 p. 253

presence of the needle sooner than he did, the Court said in part

"The total length of time which elapsed between the operation, and giving plaintiff the information concerning the needle's presence, was six weeks. More than two of these were spent in the hospital and when she left it she was removed in an ambulance. Thereafter recovery seems to have been rapid, and within a little more than three weeks after she returned to her home, and within ten days after she first appears to have been able to go to defendant's office, he informed her fully concerning the facts and the necessity for removal. We cannot say as a matter of law that defendant should have informed her earlier, or that a jury would be justified in finding that he should have done so. He acted with reasonable promptness in view of all the circumstances and a verdict that it was negligent for him not to do so earlier, on the

evidence here presented, hardly could he sustained. The mere fact that plaintiff suffered pain from the needle during the period prior to its removal does not make the failure to remove it earlier negligent. In addition to the shortness of time, it must be remembered that her physical condition for at least ten days following the operation was serious, her tendency toward nervousness was high, and the location of the needle in the fatty tissue made danger of infection or movement to a zone of danger slight. In these circumstances there was no need for haste, and there may have been real need for delay sufficient to assure that excitement or psychological disturbance incident to the removal would not cause a relapse in the patient's physical recovery. In the light of these facts the evidence indicates that the delay was not negligent rather than the contrary."

Inquiries

YOUR counsel recently received the following inquiry

"Dear Mr Brosnan

"At one of our intern conferences the question came up. Is an intern, as an individual, liable to be sued for malpractice for any act performed while serving as an intern in the hospital? If sued, is he personally liable for any judgment obtained or is the hospital liable for an judgment obtained?"

Very truly yours,"

Your counsel's reply was as follows

"Dear Doctor

"I acknowledge receipt of your letter in which you ask certain questions which have arisen at one of your intern conferences

"Your first question is 'Is an intern as an individual liable to be sued for malpractice for any act performed while serving as an intern in the hospital?' There is no question but that an intern may be personally sued for malpractice in connection with the personal care by him of a patient while serving as an intern. In my experience, in certain instances, interns have in fact been named as party defendants in malpractice actions. They are responsible to patients personally treated by them under the same rules of law as would be physicians who are members of the attending staff of the hospital. Undoubtedly, the reason why interns are not more frequently sued is that attorneys realize that interns are rarely financially responsible

"Your second question is, 'If sued, is he personally liable for any judgment obtained, or is the hospital liable for any judgment obtained?' If a judgment is rendered against an intern in a malpractice action, which is a perfectly possible outcome of such an action, the judgment would be collectible from the intern personally. Unless the judgment were directly rendered against the hospital as a party defendant, it would not be responsible for the judgment. In other words, a hospital is under no legal obligation to indemnify an intern in the event

of a malpractice judgment rendered against him personally

"It should also be pointed out that in ordinary cases, when a hospital is directly sued on the theory that one of its interns committed malpractice in the care of a patient, a hospital is not ordinarily liable for the negligent acts of the intern, provided it has used due care in seeing that the intern was properly qualified to act as an intern, and further provided that the hospital did not delegate to the intern duties which were not properly within the scope of an intern's duty

Very truly yours,"

A recent inquiry addressed to your counsel was as follows

"Dear Mr Brosnan

"I would like to have your opinion on the following. *First* If I refer a patient to another doctor, am I responsible for the treatment or operation? *Second* If when on vacation, my telephone calls are referred to another doctor who is a clinical assistant, appointed by the Board of Trustees of a hospital and has no connection with me or my personal practice, financially or otherwise, would I be responsible for any acts of this doctor in connection with a case I have never seen?

"For any service rendered by this doctor, collection is made by him direct as his own patient, in which I have no interest. Personally, I cannot see how I would be any more responsible than if you sent a client to another attorney

"Thanking you in advance I am,

Yours truly,"

Your counsel's reply was as follows

"As a general proposition the answer to both of the questions propounded in your letter is that you would not be responsible for the acts of the other physician, as in the eyes of the law you and the other doctor are independent contractors, each responsible for his own act but not for the act of the other

"To the general rule, however, there may be

exceptions as each case must be determined on its own facts. For this reason it is not possible in advance of the facts of any given case to say

whether responsibility would attach to you or not

Very truly yours,"

NEW M D'S TO BE LIEUTENANTS

"All senior medical students graduating from fully accredited medical schools in the United States this spring will be afforded the opportunity of being appointed first lieutenants in the Medical Corps Reserve of the Army," the *Journal of the American Medical Association* for April 19 reports in its Medical Preparedness Section. "The students who did not pursue formal instruction in the Reserve Officer's Training Corps will be eligible for appointment in the Medical Corps Reserve on a par with those students who did have the advantage of such instruction.

"These appointments will be made by the War Department on the recommendation of the dean of each approved medical school and on his certification that the applicant will be granted the degree of doctor of medicine on a specified date. At those schools which require a hospital internship for such degree, appointment will be made on certified evidence of the prospective successful completion of the prescribed four-year course of medical instruction. Commissions and letters of appointment will be delivered on graduation. The newly commissioned Medical Reserve officer should then present his letter of appointment to his local Selective Service board for reclassification.

"No medical Reserve officer is considered eligible for extended active duty until he shall have completed at least one year of postgraduate hospital internship. Therefore, members of this year's graduating class who are appointed in the Medical Corps Reserve, either through medical units of the R O T C or under the aforementioned procedure, will not be available for active duty until July, 1942. Deferment of such duty beyond that time will depend on the current requirement for medical officers.

"In view of the anticipated annual demand for approximately four thousand Reserve medical officers to replace those who have completed twelve months' training and service, it is doubtful that such deferments will be possible.

"The War Department approved appointment of senior medical students on February 18, and appropriate instructions were directed to the commanding general of each corps area. The deans of the several approved medical schools will receive complete instructions, together with appropriate application blanks, in the near future from the commanding general of the corps area in which the institution is located."

REFUGEE PHYSICIANS

Dr Alfred M. Hellman, president of the New York County Medical Society, writes to the *New York Tribune* to reply to another correspondent on the subject of refugee physicians as follows:

In your "Letters to the Editor" column you published on March 24 a communication signed "Medico" in which the writer complained that refugee physicians are supplanting other physicians in New York City, and notably so in the Borough of Manhattan. Since the writer of this letter referred to the membership of the Medical Society of the County of New York, I trust you will permit me to comment on this matter.

To begin with, we need to bear in mind certain basic facts. There are in the Borough of Manhattan, all told, approximately 8,000 physicians. The population of Manhattan as given is 1,871,474. This establishes a ratio of one physician to every 221 individuals. The medical schools in Manhattan graduate annually approximately 350 men and women.

These figures are significant, for it is against them that we must set the facts bearing on the refugee physicians, who, having passed the state board examination of the Regents of the State of New York, are licensed to practice in New York. Full citizenship is not a prerequisite for licensure by the Department of Education in any of the professions other than law.

As to the application by refugee physicians for admission to membership in the Medical Society of the County of New York, the following figures are pertinent. During the year 1940 the number of members elected were 283, of these only 82 were refugee physicians. Ten years ago, i.e., in 1930, the total admission to the society was 198.

That "Medico" found thirty-one refugee physicians among the list of forty-three applicants for admission to the Medical Society of the County of New York may be accounted for in part by the fact that the applications of refugee physicians for membership in the Medical Society of the County of New York are published thrice before they are acted on. While it is true that "many capable American physicians who have practiced in New York are steadily losing patients," it is not at all reasonable to charge these conditions to the entrance into our community of refugee physicians. The reason must be sought for elsewhere.

DON'T LET IT DIE

We know that in private practice, faith plays a great part in cure when it overcomes fear. This faith causes the patient to follow his physician's bidding and can only be found where the present type of practice prevails.—B J. Banton, M D, president, *Minnesota State Medical Association*

Woman's Auxiliary

To the Medical Society of the State of New York

County News

Columbia. The June meeting of the auxiliary was held at the home of Dr and Mrs John L. Edwards. Fifteen members were present for the business meeting. The president, Mrs Robert L. Bowerhan, of Copake, presided. A letter of appreciation was read from the board of directors of the Physicians Home for the \$10 recently contributed. Mrs Bowerhan and Mrs W. D. Collins reported on the Convention. The final sum of \$317 was realized from the dance given by the auxiliary for the benefit of the Hudson branch of Bundles for Britain.

At the close of the business meeting the auxiliary was hostess at a delightful tea given in honor of the graduating class of the School of Nursing of the Hudson City Hospital. The house was beautifully decorated with roses from the Edwards garden. At the tea table were Mrs Robert L. Bowerhan, Mrs Louis Van Hoesen, Mrs Clark G. Rossman, Mrs O. H. Bradley, Mrs Hugh G. Henry, Mrs W. D. Collins, Mrs Everett A. Jacobs, and Mrs Heinz Salm. Guests included the members of the graduating class, the faculty of the hospital, the auxiliary, and Mrs Masheke, Mrs J. Rider Cady, Dr Elah Bliss, and Mrs Helen Durham.

Erle. On June 24 the season closed with the annual Guest Day. Mr James A. Whitmore, manager of the Buffalo City Planning Association, was the guest speaker and talked on "Buffalo Looks Ahead." Preceding the talk a round-table luncheon was served. Mrs Carlton E. Wertz presided at the business session. Mrs William Rennie was general chairman of the enjoyable event which was purely social. There were prizes for golf, which was played in the morning followed by a buffet luncheon and an afternoon of cards in the Meadowbrook Golf and Country Club. Mrs Alan E. Richter was co-chairman, transportation was arranged by Mrs Andrew J. Charters and Mrs Walter L. Machemer, golf activities were directed by Mrs Frank G. Wolz and Mrs Elmer T. McGroder, flowers, Mrs Wertz and Mrs Harold B. Johnson, prizes, Mrs Wendell P. Reed and Mrs Jerome J. Glauber, tickets, Mrs Donald R. McKay and Mrs Joseph C. Scano, reception, Mrs Edward Villaume and Mrs Joseph P. O'Brien, reservations, Mrs Edward S. Buffum and Mrs Clarence J. Durshordwe.

Oswego. The annual luncheon was held at the Morrill tea room in Fulton. Mrs John L. Mason, of Pulaski, presided at the business session at which the following officers were elected: Mrs Harold F. McGovern, of Fulton, president, Mrs A. J. Cinsotta, first vice-president, Mrs Joseph B. Ringland, second vice-president, Mrs F. Edward Fox, treasurer, Mrs William Fivaz, assistant treasurer, Mrs D. D. O'Brien, recording secretary, Mrs Umberto Cimulodoro, corresponding secretary, Mrs William Fivaz, assistant corresponding secretary, Mrs John L. Mason, Mrs A. B. Thompson, directors. Reports were given by committee chairmen and a decision was made to give two Girl Scout scholarships to

the Scout camp, selection of the girls to be made by the executive adviser of Girl Scouts. Nineteen members were present. About 300 children of preschool age received immunization against diphtheria in the three-day toxoid clinic held in Oswego schools. This clinic is sponsored each Spring by the Woman's Auxiliary. Mrs G. A. Marsden, Mrs J. J. Riley, Mrs H. J. La Tulip, and Mrs J. J. Brennan assisted. Dr G. A. Marsden, health officer, expressed his thanks to the Department of Education, Dr Adele Brown, of the school system and to the auxiliary who assisted.

Saratoga. Sponsored by the auxiliary, a *Mental Health Institute* was held on May 22 at the Saratoga Springs High School Auditorium. Mrs T. E. Bullard, president of the auxiliary, welcomed the afternoon audience and emphasized the importance of the institute. Mrs Bullard then introduced Dr Thomas J. Goodfellow, chairman of the advisory board, who presided. Dr Frances E. Vosburgh, of the State Department, spoke on "Adjustment Problems of the Adolescent Girl." Dr D. Ewen Cameron, professor of neuropsychiatry at the Albany Medical College and director of the Moshier Division of the Albany Hospital, was also a speaker. The evening session was attended by over 300 people. Dr M. D. Duhy, vice-president of Saratoga County Medical Society, was the chairman. Dr Kathryn L. Schultz, clinical assistant at the Albany Hospital and psychiatrist for the New York State Training School for Girls at Hudson, was one of the evening speakers. Dr Frederick L. Patry, of the State Department, gave an address on "Understanding and Management of the Emotions."

Dr Cameron advocated the formation of local councils of social agencies as forming the core of a group interested in the human side of the community. He said "The experiences of every country with which we have been in contact have shown that where the individual can feel he has contributed actively and meaningfully, his insecurity and apathy subside. Our progress to new and more satisfying living depends in great measure upon the success which attends our efforts to deal, in collaboration with other social sciences, with this great problem of community social health during the present crisis and the years beyond."

Dr Vosburgh made the statement that "An adolescent girl may be the joy and pride of her parents and teachers or their despair, for her behavior is unpredictable. She may be criticized for irresponsibility, carelessness, for being boy-crazy, or for being too shy and not mingling with others. It is very necessary to maintain a good hygienic routine during the adolescent years with particular reference to rest, food, and exercise."

It was brought out that during the last few years there has been an increasing number of cases of tuberculosis in girls between 15 and 20.

Q I've noticed that some cans are golden-colored on the inside. Why is that?

A. You've probably noticed that kind of lining on cans for colored products. It's put there to protect their quality principally from a color standpoint. You'll also notice it on certain vegetables and meats. For other products, a plain tin lining is entirely suitable. The lining of the can is adjusted to the needs of the individual food. These can linings are special inert enamels baked onto the tin plate at high temperatures. ⁽¹⁾

HOW MANY PHYSICIANS?

According to Dun & Bradstreet statistics, at the
beginning of 1941 there were 144,048 physicians of all
ages and kinds in the United States

Some 37,000 were located in towns under 5,000 popu-
lation and almost 107,000 in cities with a greater popu-
lation

Almost 22,000 were over 70 years of age, more than
47,000 were over sixty, and some 60,000 were over
fifty-five Fifty-seven per cent were under 55 years of age

General practitioners comprised only 91,271 of the
total number Of these, 14,000 plus were over seventy,
almost 30,000 over sixty and over 39,000 were older than
fifty-five years of age

If all these figures are reasonably correct then we may
assume that there are 52,777 specialists in the country,
about forty per cent of which are over 55 years of age

as compared with 44 per cent in the general practice
group

Specialists listed are Dermatologists, Eye, Ear,
Nose, and Throat, Gynecologists, Industrial Surgeons,
Obstetricians, Osteopathic, Pediatricians, Public Health,
Roentgenologists, Surgeons, Tuberculosis, and Urolo-
gists

In their order of rank as to numbers, Surgeons come
first with 15,715 and Osteopaths second with 9,485
Next in rotation are Eye, Ear, Nose and Throat
specialists with 6,906, Gynecologists with 4,834, Pedia-
tricians with 4,297, Obstetricians with 2,423, Urologists
with 4,211, Roentgenologists with 2,088, Industrial
Surgeons with 1,424, Dermatologists with 1,226, Tub-
erculosis specialists with 1,187, and Public Health doctors
with 1,152

THEODORE W. NEUMANN, M.D., Phys in Chg
CENTRAL VALLEY, Orange County, N. Y.

(Continued from page 1402)

The authorities do not know why, but suspect that the combination of three factors contribute toward making girls more susceptible than boys to infection. These are too little rest, unwise dieting, and chilling of the body by inadequate clothing in winter.

Dr Patry advised us to cultivate humor as a balancing factor. "Control of emotions is more fundamental than knowledge. It makes for essence of living." Dr Schultz, in discussing the problems of women, said that "Women in business have much the same problems as men, with other problems added. Many women have a heavy family responsibility, manage their own households and have to go to business, find themselves at a disadvantage because of the social attitude toward the women who have to work, and have little time for leisure." She said

one constructive thing the depression has done was to keep fathers at home, forcing back on them part of the supervision of children. Dr Edward J. Callahan closed the institute with this advice: "Make each day pay, each day do something worthwhile, each day start fresh, and each day have some fun." The committee in charge of the institute was Mrs John A. Esposito and Mrs Harry L. Loop, chairmen, Mrs Merritt E. Van Aernem, Mrs Webster M. Moriarta, Mrs G. Scott Towne, Mrs Walter S. McClellan, Mrs Robert Harrington, Mrs H. Dunham Hunt, Mrs Thomas E. Bullard, Mrs. Ralph Post, Mrs George Green, Mrs J. M. Purcell, Miss Katherine Mezera, Miss Addie Farwell, Mrs Richard Lindsay. The advisory board was Dr Goodfellow, Dr Callahan, and Dr Earl H. King. Visitors were from Albany, Schenectady, and other towns throughout the county.

"ORCHIDS TO DRAFT BOARD PHYSICIANS"

That is the rather attractive title of a brief article by Dr Reginald A. Higgons, president of the Medical Society of the County of Westchester, in the society's *Bulletin*, noting that Colonel Leonard Rowntree, chief of the Medical Division of the Selective Service System, paid a glowing tribute to the medical profession of the United States for its assistance in the administration of the Draft Law. Colonel Rowntree stated that more than 98 per cent of the medical work of the Selective Service System is being done on a voluntary basis by doctors who receive no financial compensation whatsoever for the many hours of work they are called upon to perform. He stated that "there is not the slightest suggestion of criticism by the Selective Service authorities of the work done by the medical examiners." He characterized the service as "nothing short of splendid."

Dr Higgons adds that "it is typical of the medical profession that this voluntary service is being rendered without the beating of drums or the fanfare of trumpets and represents just another contribution on the part of the medical profession to the welfare of the community."

The *Bulletin* also notes that high praise for the work of the New York State physicians who are serving as local board medical examiners was given by Brigadier General Ames T. Brown, New York State Director of Selective Service.

"The local board physicians are not paid for their work," said General Brown. "They are doing a tremendous job and doing it exceedingly well, as their patriotic contribution to the national defense. Busy as most of them are with their private practice, they are giving freely of their time for this additional task and even allowing it to interfere seriously with their private activities and income."

"The high early percentages of induction station rejections tended to give the public an erroneous impression that the local board physicians were sending the wrong men to the Army. This was an injustice to the physicians, for not only has the percentage of rejections diminished rapidly but these percentages never did reflect the situation accurately."

"From the start of the first call up to March 1, only 2,762, or 17 per cent, of the 13,035 regis-

trants delivered by these local boards were rejected at the induction stations. Yet this period includes the most difficult months of the physicians' task."

"Differences in interpretation of requirements had to be discovered and ironed out. Each board started out with one examining physician, but after the first call more were added wherever it was found that a job was too much for a single examiner."

"The doctors, overworked and rushed, had to select their men and send them before an induction station board of specialists, supplied with equipment and facilities which the local board physician did not have at his disposal, except in a very few cases where hospital facilities were available."

"On the one hand was the necessity for striving to find as many Class 1-A men as possible, to insure meeting quotas, and on the other hand the Army was exercising the utmost selectivity because it was desired that the first inductees be the physical cream of the crop, many of them being intended for assignment to military detachments already well advanced in their training."

"In spite of all this, the doctors made an excellent record of picking the right men to prove acceptable to the Army, especially when we realize that the difference between a completely acceptable trainee and one who is not, often is a very thin line, a matter of opinion only."

"Even the 17 per cent of rejections for the first three months does not tell the true story, inasmuch as many of the rejections were of a temporary character. Some of the men listed as rejected simply were given a 1-B classification, being sent back to the boards with instructions to deliver them again when the Army calls for men for limited or special service. Some were rejected only to return later, after having certain dental or other treatment, and were then accepted. The rejections also included those who reported suffering with a fever or injury or other temporary disability, but who were delivered again in a later call and accepted. Some rejections, too, were for language difficulties or on moral or legal grounds and, therefore, were no fault of the doctors who approved their physical condition."

SANITARIUM ATTRACTIVENESS

Hotels sell themselves with a strong appeal to luxury,
 comfort, congenial atmosphere, beauty in architecture,
 etc. And though the prospect should be primarily
 interested in the possibilities of restful nights, cleanli-
 ness and decent food—the physical appearance of the
 hostelry seems more important.

No one thinks of the sanitarium in terms of attracting
 people, yet the patient differs little from the hotel patron.
 He or she looks at the appearance of the place and takes
 for granted that the facilities and ability of the staff are
 all they should be or the physician would not have

recommended the institution

A run-down place, hotel or sanitarium, would attract
 neither a patron nor a recommendation. One of the
 outstanding things about sanitariums is that almost
 without exception they are "estates" with beautiful
 buildings, lovely gardens, and lawns. Often they are
 even superior to what a patient is accustomed to.

Therefore, the physician recommending a sanitarium
 has little to fear with reference to pleasing his patient
 as to its physical pleasantness, and even less as to its
 general ability to care for a particular case.

REVIEWED

Malignant Disease and Its Treatment by Radium By Stanford Cade, F. R. C. S. Quarto of 1,280 pages, illustrated. Baltimore, Williams & Wilkins Company, 1940. Cloth, \$10.

This is an ambitious volume compiled as a textbook for the treatment of malignant disease by radium for use of the specialist in cancer therapy. The book is divided into three parts. The first part deals with the physics of radiation, the second part with the biologic effects of radiation, and the third part with the natural history and treatment of malignant disease by radium.

The physics of radiation is treated in a lucid way. This work contains several contributions to the physics of radiology, notably isodose curves for various strengths and length radium needles. It also presents a detailed discussion of radium dosimetry and conversion factors for radium dosage into equivalent r units. The reviewer agrees wholly with Dr. Cade's and his co-workers' insistence that the ideal description of radium dosage would be in terms of equivalent r units delivered at the tumor site over a stated period of time. Unwittingly perhaps, Dr. Cade recognizes the difficulty in always being accurate in calculation of radium dose—to wit, "distribution of radium on a plaque—decided by the clinician intuitively." This, of course, is contrary to the accurate work of Patterson and Parker and others. Few workers in the field have had the opportunity that Dr. Cade has had in the use of the 4-Gm radium pack. Therefore, his discussions of the physical factors, dosage system, and in the third section his clinical experience in the use of the radium pack makes doubly interesting reading. The second section dealing with radiation biology is well written and readily readable but contains nothing essentially new.

The third section shows the amazing quantity of material that Dr. Cade's many years of experience has covered. The clinical descriptions of disease are well written and not too lengthy. Now and again the reader will run into valuable and homey dicta borne out of extensive experience.

In discussing radium therapy of the various malignancies, instructions for radium technic and radium dosage are explicit, detailed, and radical. His doses are always large, frequently much larger than those used or reported by other workers. The results of treatment are far better than those in the experience of the reviewer. For instance, in his chapter on the treatment of metastatic carcinoma in the glands of the neck the author states, "The disappearance of masses of glands in the neck secondary to squamous cell carcinoma of the mouth can be obtained in 60 per cent of the cases. Recurrences take place in one-half of the cases treated." The usual experience is far below this.

The faults of the book are twofold. First, the statistics presented are sparse, incomplete, and not broken down so as to allow for comparisons

with the experiences of the reader. Second, the problem of radiation therapy is considered essentially from the point of view of the radium therapist and the interrelated problems of x-ray therapy are touched only superficially. In practical experience it is impossible to separate these two fields to the degree that the author does.

All in all the book is good, diligent, and wide in its scope.

ASA B. FRIEDMAN

Electrocardiography in Practice By Ashton Graybiel, M.D., and Paul D. White, M.D. Oblong Octavo of 319 pages, illustrated. Philadelphia, W. B. Saunders Co., 1941. Cloth, \$6.00.

Graybiel and White have written an excellent practical introduction to electrocardiography which can be highly recommended to those beginning its study. The first section of the book consists of sample records, case histories, and interpretations which serve as the text of the volume. The second half of the book is devoted to numerous practice tracings, without labels, the case histories and interpretations being on other pages.

The authors have emphasized that clinical electrocardiography is as yet largely empirical and have made their interpretations with commendable conservatism, avoiding the dogmatic and controversial. They have achieved their aim of writing a "practical" text. Theoretic considerations are carefully avoided, too much so in this reviewer's opinion.

The volume is clearly printed and the quality of paper and binding is praiseworthy, but there is much waste space. It is to be hoped that with future editions the publishers may find some way of avoiding the awkward size of the present volume. If details of taking electrocardiograms and interpretative technic were included, this would indeed be a complete text for the beginner. However, at the present writing it is the best book of its kind available. There should be a special word of praise for the admirable analytical index in the appendix.

MILTON PLOTZ

The Era Key to the U. S. P. XI & N. F. VI Fifth edition revised by Lyman D. Fonda. 16 mo. of 320 pages. Newark, The Haynes & George Co., 1939. Cloth, \$1.00.

The fifth edition of this reference book, first published in 1893, is of principal interest to the pharmaceutical student. It contains in abbreviated form an alphabetical list of drugs, chemicals, and preparations of the U. S. P. and N. F., giving their Latin and English titles, dosage, active constituents, therapeutic action, and the official preparations of the drugs. Some new sections have been added to increase the scope of the book.

VOLUME 41

JULY 15, 1941

NUMBER 14

Editorial

The Future of Medicine

It is important that physicians who are interested in the development of medicine in the United States assess and weigh carefully the relative importance of the pressures that at present are molding both practitioners and institutions of the medicine of the future. Two pressures are now operating simultaneously, each originating from a common source but with different intensities and each creating a different kind of mold because of the peculiar problems involved.

These pressures stem from the foreign and the domestic policies of the government. During the last eight years radical changes have been made in the mold of American medicine by the operation of the domestic policy of the government. Enormous pressures have been exerted upon medicine by the mass of new legislation. Responding to these legalistic pressures, medicine has materially altered its shape. But it has done so at a relatively slow pace. Legislative enactments, however, have been rapid. The impact of these rapidly accumulating legislative pressures on the relatively slow-moving body of medicine has produced within it many torques and stresses.

These stresses and torques have had little time to resolve themselves. The domestic policy of the government has been one of rapid progression toward a socialistic state, with frequent reallocations of powers and functions between the administrative, the legislative, and the judicial branches. All of these branches

of government exercise influence and exert pressure upon the body of medicine and mold its habits and practice. The ultimate fate of medicine resides in the body of law that governs it and defines its responsibility and accountability. At present it is too complex.

It may be seen then that much pressure has come to bear upon medicine due to changing concepts of the relationship between government and governed—that thing or state of mind that is called the domestic policy of government. The structural and postural changes in medicine by which it has sought to adapt itself to the new conditions have been only partly accomplished. For example, medicine has not wholly adjusted its thinking and practice to the acceptance of the support of the people by their government and to the practices that of necessity flow from this concept. Other major problems arising from altered economic concepts and practices are still but partly solved and seemingly will be still further delayed in their solution, if not thrown out altogether, by the recent abrupt change that has precipitated the Nation into a war economy.

It is the foreign policy of the government, precipitating the abrupt change to a war economy, which is now shaping, and will continue to alter further, the future of medicine. The pressures of military necessity are now replacing, or more properly adding to, the already existing stresses occasioned by the al-

[Continued from page 1406]

The Chronicle of Crichton Royal (1833-1936) Being the Story of a Famous Mental Hospital during its First Century, and Illustrating the Evolution of the Hospital Care and Treatment of Mental Invalids in Scotland. By Charles Cromhall Easterbrook, M.D. Quarto of 663 pages, illustrated. Edinburgh 12, Scotland, Murrayfield Hotel, The Author, 1940. Cloth, 25/.

This 660-page book describes the establishment, development, and growth of a famous mental hospital in Scotland during the first century of its existence. There is an account of the development of the mental attitude of people toward the treatment of the mentally sick. It discusses the various groups of people interested in the establishment and maintenance of this institution and the different laws established for the management of the mentally sick and narrates the progress made in these directions. There are many illustrations and photographs which are graphic presentations of the development of this large institution.

This volume may well be designated as an authoritative and illuminating account of the progress of psychiatry in Scotland and in England during the last one hundred years.

This book should have a wide appeal to those who are interested in psychiatry and in the history of medicine in general.

IRVING J. SANDS

Diseases of the Digestive System. Edited by Sidney A. Portis, M.D. Octavo of 952 pages, illustrated. Philadelphia, Lea & Febiger, 1941. Cloth, \$10.

This new book edited by Dr. Portis is a concise résumé of facts more recently brought out in the field of gastroenterology. It is the result of collaboration by fifty authors, each writing expertly on his particular subject. The rapid growth of gastroenterology has made the old form of textbook (to use the editor's own adjective) archaic. So vast has been the accumulation of facts, that it would be difficult for one person to present the subject in its entirety.

The relationship of the digestive tract to the anemias is well presented in a short chapter.

A section dealing with the dietetic concepts of gastrointestinal diseases is particularly lucid and scientific.

A matter that is much misunderstood by the average physician is the relation of the teeth and dental disease to the digestive tract. This subject is authoritatively treated in a compact chapter.

Much research in late years in the field of liver physiology has altered many of our ideas of liver pathology and its treatment. The exposition of liver function, the more recent tests, the modern classification of liver pathology, and the latest conception of diet are all included.

Other sections worthy of note are those on allergy, regional ileitis, dysentery, diverticulosis, and gastrointestinal tuberculosis. A selected bibliography is supplied for those who wish to extend their reading on any subject.

This volume assembles a wealth of detail, most of it new and presented by writers each proficient in his own field. It is decidedly a product of the

west and middle west with a few contributors from Boston and New York.

HENRY F. KRAMER

Laboratory Text in Pharmacology. By Robert P. Walton. Quarto of 85 pages. Philadelphia, J. B. Lippincott Co., 1940. Paper.

This treatise is a collection of experimental exercises intended to serve in a supplementary manner to the more complete laboratory manual and standard texts. The exercises are adaptations of well-known experiments, and references are made to identify their origin. It is a useful text for students who wish to review a brief summary of the usual pharmacologic experiments without consulting the more voluminous books on the subject.

FREDERICK SCHROEDER

Diagnosis and Treatment of Menstrual Disorders and Sterility. By Charles Mazer, M.D., and S. Leon Israel, M.D. Octavo of 485 pages, illustrated. New York, Paul B. Hoeber, Inc., 1941. Cloth, \$6.50.

This book is written by teachers of wide experience who have made many contributions to our knowledge in this field of medicine. It is primarily written with a view of the needs of the general practitioner, as emphasis is placed on treatment easily handled in the office rather than at the hospital. Ordinarily, menstrual disorders are explained and interpreted under the heading of the various and diverse pathologic conditions responsible for their appearance. As the authors say, "Clinically, it is more expedient to discuss these symptoms as if they were distinct pathologic entities, not only because they are, in most instances, the only manifestations of the morbidity in question, but also because each of them is so often the sole sign of multiple, co-existing and totally unrelated pathologic conditions." Very often the cause of amenorrhea or uterine hemorrhage is not discernible by all the means at our disposal, and the patient must of necessity be treated symptomatically.

The therapy is conservative, measures employed with success as measured by past experience. At the end of each chapter is a bibliography complete enough for practical purposes. It is a useful book for the average physician.

F. B. DOYLE

Surgical Anatomy of the Head and Neck. By John F. Barnhill, M.D., and William J. Melinger, M.D. Second edition. Quarto of 773 pages, illustrated. Baltimore, Williams & Wilkins Company, 1940. Cloth, \$15.

This book may well be called the otolaryngologist's primer, it is being used extensively by candidates for certification by the American Board of Otolaryngology. It covers the fundamentals of surgical anatomy quite completely. The illustrations are numerous, most are extremely valuable.

The second edition of the finest book of its kind deserves the enthusiastic reception it is enjoying. It should have a place in the library of all physicians who are in any way associated with otolaryngology.

M. C. MYERSON

reduced to one-quarter of that of the previous year, a saving of £12,000 "

We commend these items to the attention of all committees on publications of our several state or county medical societies

British Medical Journal

"Production and distribution of the *Journal*, though beset by many difficulties, have continued during the second year of war. The air raids upon London and the shortage of paper had to be contended with. Conditions of life and work during the heavy bombardments imposed a severe strain upon all engaged in producing the *Journal*. To meet the reduction in paper supplies, and the high cost of paper and postage, economy of space is effected wherever practicable, and the overall size of the *Journal* has been kept down. The inflow of original articles shows little decline in volume and far exceeds the capacity to print them. The number of letters for publication continues very large indeed, and correspondence has occupied much space so that members may have full opportunity of recording experience and putting forward their views on the great variety of topics that keenly interest the profession in wartime. The principle followed in choosing material for publication is to give preference to that which has topical interest and value, and to afford medical men and women information and guidance which will increase their ability to serve the country. Thus the pages of the *Journal*, week by week, play an indispensable part in promoting the profession's war effort and in giving it a forum to discuss the problems of to-day and to-morrow. The *Supplement*, though much cut down in size, gives prominence to War Notices issued by the Central Medical War Committee and publishes miscellaneous information which must be brought to the attention of practitioners in wartime when other means of communication and discussion are limited or cut off. Advertisements have diminished in bulk, but that has been more than offset by the higher charges for advertising space.

"Early last autumn, when things were at their worst in London, the *Journal* ended its 100th year of continuous publication, and the event was signalled by a Centennial Number dated October 5, 1940. This, though of modest size and scope, contained some historical matter and many gratifying messages of congratulations and good will from leaders of the profession at home and over-seas "

To the courageous and hardy editors of the *British Medical Journal* we extend our felicitations and admiration (as of early last autumn) upon its first, and we hope its most difficult, one hundred years of continuous publication. It has set a standard that compels our admiration and greatest respect.

In view of the President's recent call for medical volunteers for overseas service, the following letter on medical manpower in Britain* should be of interest to our readers.

"Sir—We have heard a great deal lately about the acute shortage of medical personnel. Will anyone courageously publish the facts? For when the facts and the truth are published there is evidence of maldistribution, muddle, and rapacity.

"The G M C informed me a year ago that the number on the Medical Register was approximately 64,500, this included aged, infirm, retired, and women practitioners, recently qualified, will make this number up to (allowing for death) about 65,500. Of these, I understand, approximately 36,000 are normally engaged in practice in England and Wales. The Services (by which we really mean the Army, as the Navy and Air Force are small numerically in comparison) would like to have, apparently, about one medical officer to every 250 fit and healthy young men, hence for 3,000,000 about 8,000 to 12,000 medical officers, the remaining 42 millions of population being left with the balance, about 24,000 to 28,000 medical practitioners, for all the other services—civil, general practice, consultant, E M S, and so on!

"Approximately half the Army medical officers are engaged in administrative, clerical, and office duties, the other half who are doing clinical work (so-called), for the most part in the United Kingdom, only treat minor maladies, all serious cases being transported to the local hospitals in their districts. Hence this horde of Army medical officers are not even dealing with, nor have they in many instances the equipment with which to treat, anything like all their cases. At home the Army is rapacious, desiring the lion's share of the nation's limited medical personnel, and having taken these thousands of medical men,

* *Brit. M. J.* 690 (May 3) 1941

terations in the domestic policy of the government

Thus, medicine is now under the necessity of meeting the problems of the mobilization while still having on its hands in an unsolved state the many previous problems flowing from abrupt alterations of the domestic policy of the Administration. Speaking before the Medical Society of the County of Monroe, May 29, 1941, Colonel Samuel J. Kopetzky, M C * said "We are handicapped by inherent barriers that have been erected by ourselves and which are mental attitudes produced by a decade and a half of national life pledged to an idealistic complacency." These mental attitudes can no longer endure, they have been already subjected to pressures and stresses, they have been caused to bulge and alter their shape in the last eight years. Now, under the impact of a foreign policy that

* See page 1487 of this issue

has imposed a war economy on the Nation, it is likely that mental attitudes as well as medical education and practice will alter rapidly and to a certain extent unpredictably.

The trend over the next few years, we think, will be toward a simplification of procedures and toward economy of effort. The elaboration and refinement that have characterized the period of idealistic complacency will not survive the mounting pressure for direct and economical action. The greater influence—namely, the foreign policy of the Nation—will submerge and engulf the relatively smaller domestic issues, to meet which much of the elaboration of procedure and refinement of thought on the part of medicine and government has arisen. We are of the opinion that the inevitable simplification, forced as a result of this newer pressure, will be beneficial to the future of medicine.

Medicine in Britain

The May 17, 1941, issue of the *British Medical Journal* carries, on page 755, the laconic

"Notice to Readers"

"To-day's issue of the *British Medical Journal* has been prepared and passed for press under conditions of very great difficulty brought about by exigencies of war. Readers and contributors are asked to overlook imperfections in the *Journal* as now printed in a different type-face, and to understand that much current material is perforce missing.

"It may now be stated that British Medical Association House suffered severe damage in one of the recent air raids on London, but work continues in all the departments."

Page 762 of the same issue is partly devoted to the question of blast protection for hospital windows.

"Air raids are increasing in their intensity, the weight and destructive capacity of bombs are greater, and hospitals are more likely to be put out of action even from a 'near-miss'. Experience has shown the need for bricking up the windows of resuscitation wards. It

is not only that destruction of windows and black-out material raises difficult problems of lighting, but the temperature of the ward may fall so seriously as to endanger the patients from that cause alone. Arguments for occluding the window-openings apply to theatres too, and, with somewhat less force, to general wards, where bricked-up windows mean difficulties of ventilation and serious interference with the patients' comfort."

From the Annual Report of Council, 1940-1941, we take these items

"Journal" Account

"In spite of severe restriction of the size of the *Journal* by the Ministry of Supply's control of paper, which reduced the space available for advertisements, the revenue from advertisements has been more than maintained owing to an increase of 50% in the rates for space made in May, 1940. Though many production costs have increased, particularly the cost of paper, these have been more than offset by the smaller *Journal*. More copies were printed, but the net cost of the *Journal* to the Association has been

Symposium on Food-Borne Diseases of the Gastro-intestinal Tract

VETERINARY FOOD INSPECTION

ORVILLE E. McKIM, Lt. Col., V. C., U. S. Army, Pine Camp, Great Bend, New York

MANY invaded countries have come to the painful realization that their worst enemies were within their own boundaries. It is safe to assert that many of the greatest enemies to human health also operate from the interior. Therefore, too much emphasis cannot be placed upon the importance of a properly balanced diet of foods that have been protected by competent inspection at their source and by supervision in their preparation. In much the same manner that modern fifth columnists use to gain entrance to vulnerable countries, exceedingly dangerous and even deadly influences enter the body by the way of the alimentary tract with food that is not even suspected of harboring and carrying with them agents that may and do cause acute illness, and, in many instances, death.

Little, if any, thought is ever given by the average person to the hazards of disease and death that lurk in foods, particularly those of animal origin. The importance and responsibility of the inspection of food is seldom referred to, and the service rendered through veterinary inspection is rarely given the recognition to which it is entitled. It is safe to assume that there are those who have never realized the protection they receive through the manifold veterinary inspection services that are rendered in national, state, and municipal public health departments. The dangers of disease being disseminated by unfit meat and contaminated milk are materially lessened and, to a certain extent, completely eliminated through competent and thorough inspection at their sources.

The Bureau of Animal Industry of the U. S. Department of Agriculture is a veterinary installation to which the veterinary profession and the entire nation can point with fully justified pride. It was originated and organized by a veterinary scientist, Dr. D. E. Salmon, who upon his death was succeeded by Dr. A. D. Melvin, under whose administra-

tion continued progress was made. Today under the direction of the incomparable executive and veterinary scientist, Dr. John R. Mohler, it stands as a model for the entire world and, using such a model as a pattern, many nations have initiated similar installations.

Many and varied are the diseases and reasons that render meat unfit for human consumption. Rejections or condemnations of meat are made for the following diseases and conditions:¹ tuberculosis, anthrax, foot and mouth disease, glanders, actinomycosis, rabies, tetanus, variola, septicemia, pleurisy, pneumonia, pyemia, black leg, osteomalacia, melanosis, botryomycosis, enteritis, peritonitis, malignant edema, metritis, leukemia, hemorrhagic septicemia, piroplasmosis, uremia, parturient paresis, pregnancy, calf dysentery, local inflammatory changes, tumors, febrile diseases, mammitis, swine erysipelas, swine plague, hog cholera, abscesses, lung worms, nephritis, endocarditis, myocarditis, pericarditis, hepatitis, liver fluke, measles, Babesia, rachitis, and anemia.

Many of the foregoing diseases and conditions are diagnosed by veterinary inspection on antemortem examination and condemned before they reach the killing floor. According to C. E. Edmonds, D. V. S.,² supervising inspector of the Dressed Poultry Inspection of Chicago, 43,550,124 pounds of dressed poultry were government inspected in the United States during the period of a year. Of these, 743,777 pounds were condemned as unfit for food. The causes for condemnation include avian tuberculosis, septicemia, emaciation, decomposition, peritonitis, tumors, leukemia, abscesses, and other conditions. Tuberculosis by far exceeded all other causes.

It is to be hoped that in the not-too-distant future the specifications of the U. S. Bureau of Animal Industry will stipulate that all chickens, turkeys, ducks, etc., must be eviscerated and veterinary inspected prior to freezing. Aside from the protection from diseases previously mentioned, much more palatable meat is provided. When chickens,

¹Read by invitation at the Annual Meeting of the Medical Society of the State of New York, Buffalo, April 30, 1941.

for the most part of £450 per annum in a rank and status equivalent to that of a sub-lieutenant R N, aged 20 years, they do not even do their own work!

"It is obvious where conibing is required In many areas general practitioners are being worked to death What has happened to the thousands of consultants and general prac-

tioners from denuded areas, whose practices have virtually disappeared?

"I am, etc,
Charles A H Franklyn, M D, M R C S"
Oxford, April 14

We commend this letter to the thoughtful consideration of the newly formed Section on General Practice of the American Medical Association

How the German Army Is Fed

The comparatively young science of nutrition—to be differentiated from the age-old art of gastronomy—is rapidly coming out of the laboratory into the kitchen—home, field, rolling, and Army Questions involving fatigue and recuperation are demanding answers as the training of the new Army progresses

Fortunately, at a time when interest in problems of nutrition is steadily growing, we are able to present on page 1471 an interesting discussion of this subject by Dr Max Gerson under the

title, "Feeding the German Army" It will be well worthwhile for our readers to peruse this article thoroughly in view of the many nutritional problems that face us here in civilian and military life

At some time we will be faced with the necessity of feeding a postwar Europe Some of the newer discoveries and practices of the growing science of nutrition may help in resolving many of the economic, as well as the nutritional, complexities of this period to which thought must be given now

Medical Director of Civilian Defense

With the announcement on July 3 of the appointment of Dr George Baehr as chief medical director in the United States Public Health Service in charge of civilian defense, the Medical Society of the State of New York is brought into ever closer contact with the defense of the Nation The announcement of Dr Baehr's appointment was made jointly by the Office of Civilian Defense and the U S Public Health Service Dr Baehr will act as chief medical officer in the Office of Civilian Defense under the Honorable F H LaGuardia, director, and will coordinate the activities of Civilian Defense and the Public Health Service Plans and facilities for disaster relief in the cities will be developed based on experience in handling these matters gained by the British

At the last meeting of the House of Delegates, the Reference Committee on the Report

of the Secretary¹ said, in part "We feel that Organized Medicine in New York State under the inspired leadership so far exhibited will not be found wanting in maintaining a concerted effort in the medical care and protection of both our armed and civilian population in this time of national emergency" The Society has good reason to feel that it is indeed being accorded the opportunity of maintaining a concerted effort in the medical care and protection of both our armed and civilian population, since it is being represented in the first of these categories by Col S J Kopetzky, M C, and now in the second by Dr George Baehr, who has served the Society so well in the recent past as a member of the Council Committee on Public Health and Education

ERRATUM

George Pollack, of Brooklyn, was listed among the "Deaths of New York State Physicians" in the July 1 issue—a mistake that we sincerely regret The name should have been Charles Pollack, also of Brooklyn, a graduate of P & S N Y, who died on March 21

Symposium on Food-Borne Diseases of the Gastro-intestinal Tract

VETERINARY FOOD INSPECTION

ORVILLE E. MCKIM, Lt Col, V C, U S Army, Pine Camp, Great Bend, New York

MANY invaded countries have come to the painful realization that their worst enemies were within their own boundaries. It is safe to assert that many of the greatest enemies to human health also operate from the interior. Therefore, too much emphasis cannot be placed upon the importance of a properly balanced diet of foods that have been protected by competent inspection at their source and by supervision in their preparation. In much the same manner that modern fifth columnists use to gain entrance to vulnerable countries, exceedingly dangerous and even deadly influences enter the body by the way of the alimentary tract with food that is not even suspected of harboring and carrying with them agents that may and do cause acute illness, and, in many instances, death.

Little, if any, thought is ever given by the average person to the hazards of disease and death that lurk in foods, particularly those of animal origin. The importance and responsibility of the inspection of food is seldom referred to, and the service rendered through veterinary inspection is rarely given the recognition to which it is entitled. It is safe to assume that there are those who have never realized the protection they receive through the manifold veterinary inspection services that are rendered in national, state, and municipal public health departments. The dangers of disease being disseminated by unfit meat and contaminated milk are materially lessened and, to a certain extent, completely eliminated through competent and thorough inspection at their sources.

The Bureau of Animal Industry of the U S Department of Agriculture is a veterinary installation to which the veterinary profession and the entire nation can point with fully justified pride. It was originated and organized by a veterinary scientist, Dr D E Salmon, who upon his death was succeeded by Dr A. D Melvin, under whose administra-

tion continued progress was made. Today under the direction of the incomparable executive and veterinary scientist, Dr John R Mohler, it stands as a model for the entire world and, using such a model as a pattern, many nations have initiated similar installations.

Many and varied are the diseases and reasons that render meat unfit for human consumption. Rejections or condemnations of meat are made for the following diseases and conditions¹: tuberculosis, anthrax, foot and mouth disease, glanders, actinomycosis, rabies, tetanus, variola, septicemia, pleurisy, pneumonia, pyemia, black leg, osteomalacia, melanosis, botryomycosis, enteritis, peritonitis, malignant edema, metritis, leukemia, hemorrhagic septicemia, piroplasmosis, uremia, parturient paresis, pregnancy, calf dysentery, local inflammatory changes, tumors, febrile diseases, mammitis, swine erysipelas, swine plague, hog cholera, abscesses, lung worms, nephritis, endocarditis, myocarditis, pericarditis, hepatitis, liver fluke, measles, Babesia, rachitis, and anemia.

Many of the foregoing diseases and conditions are diagnosed by veterinary inspection on antemortem examination and condemned before they reach the killing floor. According to C E Edmonds, D V S,² supervising inspector of the Dressed Poultry Inspection of Chicago, 43,550,124 pounds of dressed poultry were government inspected in the United States during the period of a year. Of these, 743,777 pounds were condemned as unfit for food. The causes for condemnation include avian tuberculosis, septicemia, emaciation, decomposition, peritonitis, tumors, leukemia, abscesses, and other conditions. Tuberculosis by far exceeded all other causes.

It is to be hoped that in the not-too-distant future the specifications of the U S Bureau of Animal Industry will stipulate that all chickens, turkeys, ducks, etc., must be eviscerated and veterinary inspected prior to freezing. Aside from the protection from diseases previously mentioned, much more palatable meat is provided. When chickens,

¹Read by invitation at the Annual Meeting of the Medical Society of the State of New York, Buffalo, April 30, 1941.

turkeys, ducks, and other fowl are frozen with the intestines left in the abdominal cavity, there is always a varied amount of grain feed in the intestinal tract. Upon defrosting, a great amount of gas is formed by the fermenting of intestinal contents. This gas permeates the carcass and leaves a none too pleasant flavor. The cost of eviscerated fowl is no greater than those frozen by the old method now rendered obsolete.

Many of the foregoing diseases are not directly transmissible to the human body in their true symptomatic picture. The clinical manifestations of the results of the majority of pathologic conditions in foods of animal origin are caused by toxins that have developed in a diseased carcass either before or subsequent to slaughter. A well-recognized example of this phenomenon is the chain of symptoms caused by the toxins of *Bacillus enteritidis* which occur within a few hours after food is eaten. In most cases it is not possible to demonstrate the causative organism because it has been killed in the cooking or canning process, yet it leaves its deadly toxins that produce gastrointestinal disturbances, varying in severity with their potency. A similar condition is encountered when victims have eaten pastries, such as custards, which have been impregnated with the toxins of paratyphoid bacillus of mouse origin.

State and municipal veterinary services protect the public from many dangers in addition to those eliminated by the Bureau of Animal Industry inspection.

Locally slaughtered animals and fowl present a problem of no small proportions because of the possibility of meat from unsound animals being sold for human consumption. Prominent among the diseases that form the chief dangers are tuberculosis, anthrax, tapeworms, actinomycosis, foot and mouth disease, and various intestinal disorders.

The greatest hazard of intestinal disorders originating in locally slaughtered animals and poultry is the meat of animals or fowl that, after death from disease or accident, have been dressed and sold for food by unscrupulous dealers. This is termed "cold slaughter," and it is easily and quickly detected by the experienced veterinarian and condemned. The toxins that develop in meat of such origin are deadly in their effects and are unusually resistant to any methods used in an effort to destroy them.

State and municipal veterinary service is also indispensable in the inspection of proc-

essed meat products offered for sale by stores and markets.

Aside from the diseases previously mentioned in connection with farm-slaughtered or locally killed meat of animal or fowl origin, a terrific hazard exists in the form of toxins that are produced in the meat by bacteria. These toxins cannot always be destroyed by heat, and a severe gastroenteritis can result from them. These cases present three phases that may or may not be sharply defined: (1) choleric cases with profuse diarrhea, (2) cases running a typhoid-like course, (3) cases beginning with choleric symptoms but soon presenting typhoid-like symptoms. Although the greatest hazard of this condition is encountered in "cold slaughtered" animals, as previously mentioned, there are also other potential sources.

Another and equally important source is the chopped meat prepared by meat dealers and sold at a bargain price. It is a Roman holiday when commercial chopped beef is mixed and ground, since everything from trimmings of fat and gristle to old wrinkled frankfurters is thrown into the hopper and their identity is lost in the resulting shuffle. Bear in mind that it is the toxins of bacteria existing in unfit meat that produce deadly results, and these toxins cannot be destroyed by heat in cooking. It is safe to assert that the Meat, Food, and Dairy Inspection service rendered by the Veterinary Corps of the U S Army is equal to any, and superior to most, army veterinary food inspection services. The veterinary officer is charged with the dual responsibility of the protection of the health of the command from the dangers that lurk in meat and dairy products, as well as the economic protection of the government through the prevention of inferior or unfit products being delivered by unscrupulous contractors or dealers.

The Government Specifications are well defined and, in order to see that these specifications are not evaded, the veterinary officer is given a specialized training to qualify him as an expert in this field. He must be able *at a glance* to differentiate between cow, bull, and steer beef. In addition, he must be able to determine the age at slaughter, type, grade, and condition of all steer beef. He must be able to differentiate lamb from mutton, chicken from fowl, and pork, ham, and bacon of pig from that of hog origin. He must be able to score butter and cheese, grade lard, and be an expert in grading and classifying eggs, detecting all types of unsoundness.

common in them. He must be familiar with all types of deterioration, spoilage and unsoundness, and other features that disqualify any and all food products that might be a menace to the health of the troops.

During the year 1938, under the competent direction of Colonel R. A. Kelsner, chief veterinarian, Surgeon General's Office, the Veterinary Corps inspected for the U. S. Army and CCC (prior to or at purchase) 372,449,561 pounds of meat, meat food, and dairy products, 359,312,444 pounds were passed and 23,137,117 pounds rejected. The estimated monetary equivalent was \$1,158,411.97.¹ Monetary equivalent represents the estimated difference in value between what was offered for delivery and rejected and the products finally accepted. When this saving of well over a million dollars is compared with the amount paid to veterinary officers over the same period, it offers conclusive evidence of the economic value of this protection and also causes the Veterinary Corps to feel fully justified in its pride of achievement. In addition to the meat and food inspection, the Veterinary Corps also performs important service through the sanitary inspection of all dairies and plants of contractors that deliver milk and food to the Army. Although not often publicized or prominently referred to, this phase of veterinary activity is indispensable.

The veterinary officer must also have a well-grounded knowledge of processed foods, such as hams, bacon, bologna, liverwurst, frankfurters, pork sausage, and seasonal viands such as summer sausage, etc.

His services are invaluable in canning plants where he supervises the canning of meats and other products. His inspection begins at the choice of the meat and other ingredients and carries through each stage until the can is lacquered and ready for shipment. During the year 1939 under supervision of the Veterinary Corps at the Chicago Quartermaster Depot for the U. S. Army and CCC 8,959,596 pounds of canned meat were inspected, prepared, passed, and accepted, while 186,063 pounds of canned meat were rejected.²

In order to perform the various duties involved in meat and food inspection, the veterinary inspector must of necessity develop all five senses to the highest degree. Keen sight is necessary to determine the condition, type, and grade of meat, eggs, dairy products, and other foods, as well as to detect any form of unsoundness or spoilage such as mold, de-

cay, sprouting, etc. The sense of smell is necessary for the detection of putrefaction, fermentation, and other abnormal odors. The sense of feeling is necessary to detect firmness or flabbiness and to determine the presence or lack of the bloom on eggs, dryness or moisture, and many other conditions. The sense of hearing is indispensable in detecting gas, vacuum, too much water or a too great amount of solids in canned foods, and in testing melons for ripeness, etc. The sense of taste is obvious.

In addition to the foods of animal and dairy origin, veterinary inspection also includes seafoods (fresh and canned), fruits, and vegetables. It will not be possible to present in detail any of the various fields covered by veterinary inspection. However, a few items of practical interest and advice for the guidance of those physicians whose practice is confined largely or entirely to diseases of the alimentary tract can be given. It is safe to assume that some of the most serious conditions encountered in this group are of an acute nature as well as of obscure origin. Upon inquiry into the history of such cases it is possible to disregard a potential causative factor through the failure to take cognizance of the momentous role played by toxins from various sources. It is safe to assert that in most cases where sudden attacks of intestinal disturbances (exhibiting as their principal symptoms, acute pain, nausea, diarrhea, prostration, and possibly coma) involve numbers of individuals, the etiologic factor is usually found to be a toxin of food origin. An enumeration of possible sources is pertinent to this discussion.

Sources of local origin may include meat from "cold slaughtered" animals to which previous reference was made, chopped beef made from scraps infected with *B. enteritidis* or becoming contaminated subsequent to being ground, veal from immature calves (bob veal) the sale of which is now legal in New York State if offered and sold as "baby veal,"³ as well as meat from sickly or infected calves previously referred to in this discussion, improperly processed meats such as bologna, boiled ham, veal loaf, etc., especially if not protected from unfavorable temperatures, potato salads that may contain a deadly poisonous alkaloid, solanin, present in immature, sunburned, and sprouted potatoes, as well as toxins developing from proteus bacillus or other bacterial contamination, and seafoods in which postmortem changes have appeared.

It is worthy of note that the poisonous toxins developing in putrid fish are more intense in their action than the putrefactive toxins in the meat of warm-blooded animals. Shell fish, such as lobsters, crabs, and shrimp, are usually the greatest potential source of seafood poisoning symptoms. Because of the shell in which the edible parts are encased, there are no means of escape for the toxins forming during preparation, and those developing in lobsters that are dead prior to cooking are the most severe in their clinical manifestations. In all ready-to-serve boiled lobsters that are purchased, care should be taken to note whether or not the caudal fin (tail) is rolled in—it is always straight if the lobster was dead prior to cooking.

Butter, cheese, and ice cream are also potential harborers of deadly toxins of bacteria, the latter two particularly adaptable to their propagation.

The recognition and serious consideration of the role played by toxins in gastrointestinal disturbances should be of primary interest in efforts made toward an accurate determination of the cause. Through the use of the Schwartzman phenomenon⁶ there is available a method by which the presence, as well as the potency, of toxins can be definitely demonstrated. Investigations conducted by public health authorities in search of the specific etiologic factors producing food poisoning symptoms in numbers of victims would be greatly assisted by the employment of this scientific and reliable technic. The utilization of the Schwartzman phenomenon should be of untold value in their efforts to fix definitely the responsibility for outbreaks by a positive proof of the source of the toxin-producing agents.

In conclusion, it is relevant to the subject under discussion to call to the attention of health authorities the protection from possible occurrences of food poisoning which is available through the use of competent veterinary meat and food inspection by having it included in municipal projects for public health preservation. In addition to the hazards of toxins that may be present in unfit meat and fish foods, there is also another food source of vital interest and importance in which veterinary service plays a prominent part. This is in the milk supply control so essential to the health of all communities. So many dangers are to be found in this universally used food, and products made from it, that serious consideration should be given to the supervision of the production, protection, and

distribution of this potential conveyer of disease. Time will not be taken to enumerate the milk-borne diseases since their presentation and discussion are of more interest to general medical practitioners. It is pertinent to this discussion, however, to draw to the attention of gastroenterologists that "cholera morbus" in children can become an unknown disease under proper veterinary control of milk sources and distribution. It is safe to assert also that many outbreaks of acute food-poisoning attacks could be reduced to a minimum by proper municipal veterinary inspection of all food offered for sale at fish and meat markets and other sources of possibly contaminated, improperly prepared, or otherwise unfit meat and dairy products. Veterinary sanitary inspections of stores, dairies, and other installations used for food distribution would serve to prevent contamination.

In countries vulnerable to attacks from the air, shelters are provided for the protection of the inhabitants from injury and death caused by unseen missiles. Is it not a logical procedure to protect the populace in peace, as well as in war, from the unseen dangers that exist in food, particularly those of animal origin? In this effort, veterinary inspection both of locally killed meats and of dairy products, as well as the other foods of animal origin, should play a prominent role. A more extensive utilization of veterinary service in municipal public health protection is advisable for humane purposes as well as for being an economically sound measure. The economic value of veterinary service has been conclusively demonstrated by the records compiled by U. S. Public Health Service, U. S. Bureau of Animal Industry, and U. S. Army, as well as many municipal departments of public health, and there can be no doubt of its necessity as a part of the humane endeavors made by public health organizations.

Discussion

Dr. E. T. Faulder, *Albany, New York* (read by Dr. J. W. Clans, *Buffalo, New York*).—I feel highly honored and especially privileged

to have been invited to discuss this excellent paper

In discussing food inspection, we immediately think of meats and meat food products so essential in our diets, and the inspection of meats and meat food products calls our immediate attention to the inspection of these products as carried on by the U S Department of Agriculture, Bureau of Animal Industry, under the Federal statute enacted in 1906

On July 1, 1940, Federal meat inspection was being carried on in 649 establishments and 251 cities and towns, cooperative service also being rendered to fifteen governmental agencies in the examination of meats and meat food products for condition in conformance to specifications

Under Federal meat inspection, both antemortem and postmortem inspections were made on 78,527,862 animals, representing cattle, calves, sheep, lambs, goats, swine, and horses, 27,208 being condemned upon antemortem inspection. Postmortem examination upon the animals subjected to antemortem inspection resulted in 223,548 being condemned. There were thirty-five different diseases involved in the condemnation of carcasses as unfit for human consumption

Throughout the many years that Federal meat inspection has been in operation—and the service is known and recognized as the most efficient of any in the world—much discussion has taken place by organized groups in the various states with the expectation that state-wide meat inspection could be inaugurated in the various states, patterned after the Federal Meat Inspection Service. The only state that has set up a state meat inspection is California, which has established an efficient meat inspection service. In New York State a committee of the New York State Veterinary Medical Association has been working on this problem for a number of years, and I am optimistic enough to believe that eventually New York will establish and maintain state-wide meat inspection to take care of the one-third of the meat-producing animals which do not undergo Federal meat inspection and only a part of which is inspected to any degree and in a limited number of places under local inspection—in many cases the inspection is not conducted by veterinarians. In the Federal Meat Inspection Service the veterinarians are appointed as a result of Civil Service examination, and this group of workers undergo constant training after entering the service

In addition to the antemortem and postmortem work done mostly by veterinarians, all meats

and meat food products under the Federal meat inspection system are done by a force of experienced and competent laymen also appointed as the result of Civil Service examination.

The number of animals subjected to antemortem and postmortem inspection under the Federal Meat Inspection Act, the number of animals condemned on account of antemortem inspection, and the number of carcasses condemned on postmortem examination because of various diseases have been pointed out. Let us now take note of the vast quantities of meat and meat food products subjected to inspection under the Federal Meat Inspection Act

During the fiscal year of 1940, 9,690,164,254 pounds were inspected. This covered products placed in cure, smoked sausage of various kinds, canned meats, bacon, lard, etc. The number of pounds of meat food products condemned because they had become sour, tainted, rancid, unclean, or otherwise unfit for human consumption was 5,035,163 pounds. These figures should emphasize the importance of the creation of a state meat inspection service patterned after the Federal Meat Inspection Service in all details. When this is done the meat-consuming public will be fully protected.

In all establishments where Federal or local inspection is maintained and where local inspection may be eventually established, sanitation should be maintained at all times. This means sanitary construction of the buildings and takes care of drainage, light, etc. The walls and floors should be constructed of proper materials, so that at the end of the day's operations all surfaces can be thoroughly cleansed by the use of a steam hose and the use of soda as a detergent. All equipment should be constructed preferably of metal, various parts should be removable and so made that all surfaces can be thoroughly cleansed as described, with no corners or crevices in which objectionable material can collect. Thus, such equipment can be kept thoroughly clean at all times, and meat and meat food products can be preserved in a sound and wholesome condition.

In connection with sanitation, controlled refrigeration is imperative for the preservation of the carcasses of meat-producing animals, meat food, and dairy products

In closing, it is desired to impress upon those interested in the protection of public health the economic value of veterinary food inspection, as well as its importance in sanitary inspections that prevent the contamination of foods intended for human consumption.

EPIDEMIOLOGY OF FOOD-BORNE DISEASES OF THE GASTROINTESTINAL TRACT

JAMES E PERKINS, M D , Dr P H , Albany, New York

I NEED hardly state that one could spend hours discussing the epidemiology of amebic dysentery, typhoid fever, or any of the other illnesses on the large list of diseases falling into this category. Therefore, I shall consider only those that are, or may become, prevalent in New York State and, furthermore, discuss only the more important or more interesting epidemiologic features of these diseases.

Since some of you may have recently thought as little about public health terms as I have about technical expressions of the gastroenterologist, perhaps I should remind you that "epidemiology" means the mass phenomenon of illnesses or, in other words, the characteristics of an illness as it occurs in the population as a whole. It involves the consideration, therefore, of such things as the age, sex, seasonal and geographic distribution, incidence at various periods of time, and similar mass features. In my discussion I shall not confine myself strictly to epidemiology, however, since there are some administrative aspects of the control of these diseases which I think will be of interest to you.

The illnesses to be discussed fall into five groups from an etiologic standpoint: those due to nematodes, protozoa, bacteria, filtrable viruses, and chemical poisons.

Trichinosis

Trichinosis is a disease caused by a nematode, *Trichinella spiralis*. The chief symptoms of trichinosis, of course, occur elsewhere than in the gastrointestinal tract but, since infestation occurs through this tract and gastrointestinal symptoms are also present to a greater or less extent, it seems proper to include trichinosis in this discussion.

In a recent article on the subject by Dr Wright of the National Institute of Health,¹ a map is reproduced showing the total number of cases reported in the various states throughout the country up to July 1, 1938. In this map New York State seems to stand in bold relief, since it is the only one in solid black denoting over 1,000 cases reported. This map does not give the proper impression

of the relative importance of trichinosis in different parts of the country, since it does not take into consideration the differing populations, the length of time the disease has been reportable, and the variation in completeness of reporting in the various states. Nevertheless, it clearly indicates that trichinosis is a problem worthy of consideration in the State of New York.

Human cases of trichinosis occur, as you know, through consumption of undercooked pork or pork products. The infestation of the hogs in the first place is apparently due chiefly to the practice of feeding them on raw garbage. The garbage contains raw pork scraps, which, in turn, contain cysts of the parasite, and thus there is completed the cannibalistic cycle that perpetuates the infestation in the hog. Although rats are highly infested, they apparently are seldom eaten by hogs and are not so important in the infestation of swine as formerly supposed. The feeding of offal to hogs is a ready means of producing infestation, but such feeding is believed rare in New York State and is specifically prohibited by law.

A minor outbreak of the disease has been experienced in 1939 and 1940. In the outbreak in the early part of 1940, 20 cases of trichinosis occurred among German-Jewish refugees living in New Rochelle and 15 cases occurred among residents of the Bronx, all of whom ate uncooked "teewurst" obtained from a company located in the Bronx. In the United States this product is ordinarily eaten only after cooking, but in Germany it is used raw as a spread, and these refugees used the product in the manner to which they had been accustomed in Germany.

The 1939 outbreak consisted of 11 cases among individuals attending a church supper in Potsdam Village, St. Lawrence County. Pancakes and pork sausage were served at the supper, and investigation revealed that the original source of the pork was the local garbage collector's piggery. The hogs had been fed on raw garbage from the municipality.

A survey of garbage disposal methods,² made by the Division of Communicable Diseases of the New York State Department of Health in 1939, revealed that about one-

¹Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, April 30, 1941.

²From the Division of Communicable Diseases, New York State Department of Health.

third of the cities and incorporated villages in New York State dispose of their municipal garbage through feeding it raw to hogs. Elimination of this procedure should result in a material reduction in the trichinosis hazard in this state.

The 1940 Legislature appointed a Trichinosis Commission to study the problem. In its report³ the Commission recommends prohibiting the feeding of raw garbage to hogs and the establishment of intrastate regulations governing pork products ordinarily consumed without further cooking comparable with the Federal regulations governing interstate shipment of such pork products. Bills were introduced in the 1941 Legislature providing for regulations to govern these two phases of trichinosis control. The bill authorizing the Commissioner of the Department of Agriculture and Markets to establish regulations governing pork products was passed, but the bill prohibiting municipalities from entering into contracts for the disposal of their garbage through feeding it raw to hogs failed to pass.

Amebic Dysentery

In the protozoan group I shall consider only amebic dysentery, due, as you know, to the *Endamoeba histolytica*.

In 1933 a certain New York City night-club hostess, famous for her candid greeting of welcome to her guests, became ill on the West Coast with what was diagnosed by her physicians as acute appendicitis. Despite a phone call from the Chicago City Health Department, a laparotomy was performed, and the night-club hostess' career came to an abrupt and untimely end. The interest in the case displayed by the Chicago City Health Department was due to the fact that it had uncovered the existence of an extensive epidemic of amebic dysentery occurring among guests of two adjacent Chicago hotels. Autopsy revealed that, as the Chicago City Health Department had suspected, the hostess' illness had been amebic dysentery.⁴

Hers was only one of over 1,400 cases discovered by that Department as a result of a follow-up of each guest registered at the two hotels. The cases were scattered among residents of forty-three states, three Canadian Provinces, and the Territory of Hawaii. The unfortunate outcome in the night-club hostess' case was a fate shared by 40 per cent of the victims who were subjected to operation because the illness was mistaken for ap-

pendicitis. The case fatality rate among all cases was only 7 per cent.

Investigation⁵ disclosed that the illnesses were due to infected drinking water. Through faulty plumbing, fresh sewage from one hotel was introduced directly into the drinking water supply of both hotels. Interestingly enough, no case of typhoid fever or of any of the other usual enteric diseases was discovered. The reason for this apparent paradox is that the Chicago water, which is derived directly from Lake Michigan without preliminary filtration, is usually quite heavily chlorinated, and the chlorine residual was apparently sufficient to destroy the usual enteric pathogens but was not effective against the amebic dysentery cysts. That both typhoid fever and amebic dysentery would occur if the water were freshly polluted with sewage in the absence of chlorination was amply demonstrated in the same city shortly afterward (May, 1934) when both typhoid fever and amebic dysentery occurred among firemen and spectators drinking from a local, heavily contaminated source of water used in fighting an extensive fire in the Chicago stockyards.⁶

The importance of the hotel outbreak from an epidemiologic standpoint is that it clearly demonstrates amebic dysentery may be an important disease in the temperate zone as well as in the tropical zone and that it may be transmitted through contaminated water as well as by food infected by carriers. The food-handling carrier was formerly assumed to be the only factor of importance in the transmission of the disease.

Bacillary Dysentery

As to bacillary dysentery, in New York State this is chiefly a disease of institutional inmates, vacationists, and rural residents, and the same may be said of illnesses due to the paratyphoid-enteritidis (*Salmonella*) group of microorganisms. Outbreaks due to *Bacillus dysenteriae* Flexner, Sonne, and Schmitz repeatedly occur among the populations of institutions, particularly those for mental patients where it is difficult to maintain good standards of personal hygiene and mentally subnormal inmates are used to assist in the preparation and handling of food. A state institution for mental defectives has been utilized during the past two years for a detailed bacteriologic and epidemiologic study of endemic bacillary dysentery, conducted jointly by the DeLamar Institute of Public Health of Columbia University and the New York State Departments of Health and Men-

covered and, in most instances, recovery was complete within a few hours after onset. *Staphylococcus aureus* was isolated from specimens of the cream puffs and, although in this instance no suppurating lesions were found on the hands or bodies of any of the cooks, nose and throat cultures revealed that one of the pastry cooks was harboring numerous *Staph. aureus* organisms in his throat secretions. The handling of the pastry was such that ample opportunity was provided for development of the toxin following filling of the pastry shells.

Ham apparently may also be readily infected by *Staph. aureus* with formation of a toxin. This seems to be particularly true of the recently introduced hams that have undergone a tendering process.¹⁰ During the past five years, 1936 to 1940, seven outbreaks totaling 85 cases have come to the attention of the New York State Department of Health in which epidemiologic evidence incriminated ham as the source and in which the illnesses were suggestive of staphylococcus toxin poisoning. In several instances, portions of the ham considered responsible were available, and bacteriologic examination revealed the presence of *Staph. aureus* in large numbers. To avoid such episodes, ham must be handled in a sanitary manner and kept refrigerated, except when actually being served, from the time the ham leaves the packing plant until all of it has been consumed.

Filtrable Viruses

I shall say little about food-borne gastrointestinal illnesses caused by filtrable viruses. Illnesses due to filtrable viruses usually are not gastrointestinal in nature. Although relatively minor, gastroenteric symptoms do occur in polomyelitis, and a few outbreaks of polomyelitis have occurred which seemed to be milk-borne.¹¹ There is ample evidence, however, that such transmission is rare indeed. With the recent demonstration of the frequency with which the polomyelitis virus may be obtained from the stools of cases,¹² the possibility of occasional food-borne and water-borne transmission of the disease must be considered.

Epidemic diarrhea of the newborn is probably due to a filtrable virus. In the investigation of an outbreak occurring in 1939 in a hospital in a city in upstate New York there was suggestive evidence that the infection may have been transmitted from infant to infant by means of improperly sterilized nursing nipples.¹³

Chemical Poisons

In conclusion, I wish to say a few words about gastroenteritis due to chemical poisons in food. In 1928 and 1929 several outbreaks of violent but transient gastroenteritis were studied in New York State, and it was found that the only thing the victims had in common was a history of having eaten at a hotel a few hours prior to onset of symptoms. No one hotel was involved and no particular article of food. Investigation disclosed that in these hotels the same brand of silver polish was being used and that the polish contained sodium cyanide. Elimination of this type of silver polish resulted in cessation of cases among guests.¹⁴ This finding resulted in the establishment of a regulation by the Public Health Council in 1929, prohibiting the use in any eating place of a polish containing a cyanide preparation (Regulation 8, Chapter XIV, Sanitary Code). No outbreaks due to this cause have been discovered in upstate New York since that time.

In December, 1939, an explosive outbreak of gastroenteritis occurred in an institution in Greene County. The outbreak was promptly reported to, and investigated by Dr. Hollis Ingraham, district state health officer of the Kingston District. A total of 69 cases occurred, characterized by headache, nausea, violent and repeated vomiting, abdominal cramps, and, in about half the cases, diarrhea. The patients developed no fever and recovered in the course of about three hours in most instances. The great majority of victims became ill within ten minutes following ingestion of the noon meal. All of the cases occurred among the 143 inmates who ate at the first serving. Many became ill before they could rise from the table and, since the chocolate pudding served as dessert was suspected as being the source of the illnesses, the second shift of 488 inmates were given canned loganberries in place of the chocolate pudding but otherwise were served exactly the same meal. No cases of illnesses developed among this latter group. A better controlled experiment could hardly have been devised, the chocolate pudding obviously was the food responsible for the illnesses, and this was further confirmed by additional epidemiologic data. The remaining pudding had been discarded, but scrapings from a pan were analyzed and it was found that fluorides were present in concentrations of 0.1 to 0.3 per cent. The only poisonous material available in the kitchen was roach powder containing sodium fluoride, and it seemed clear

TABLE 1—REPORTED CASES OF CERTAIN COMMUNICABLE DISEASES NEW YORK STATE, 1931 TO 1940 INCLUSIVE

Year	Number of Cases			Cases per 100 000 Population				
	Trichinosis	Amebic dysentery	Bacillary dysentery	Typhoid fever	Trichinosis	Amebic dysentery	Bacillary dysentery	Typhoid fever
1931	90		167*	1,133	0.7		1.3*	8.9
1932	69		186*	1,049	0.5		1.5*	8.2
1933	145	87	253	976	1.1	0.7	2.0	7.6
1934	198	107	561	670	1.5	0.8	4.3	5.2
1935	241	56	743	631	1.8	0.4	5.7	4.8
1936	170	54	489	592	1.3	0.4	3.7	4.5

1940	274	61	845	276	2.0	0.5	6.3	2.0

* Amebic and bacillary dysentery were not tabulated separately prior to 1933

that some of the roach powder had been introduced into the pudding

During the past three years the New York City Health Department has uncovered four outbreaks due to a relatively new food poisoning entity, cadmium poisoning,¹⁵ and Dr Samuel Frant of the Department has kindly permitted me to mention the results of their investigations. The illnesses apparently are similar to those observed in the fluoride poisoning outbreak, with symptoms developing within a few minutes after ingestion of the responsible food or drink and consisting of nausea, vomiting, abdominal cramps, and diarrhea. With one exception, the food or drink responsible was found to be acid in nature (raspberry gelatin dessert, commercial "lemonade" powder containing tartaric acid, and iced tea prepared with lemons), and the preparations had been made in cadmium-plated metal vessels (refrigerator trays or pitchers). In the one exception, ice cubes from a cadmium-plated refrigerator tray had been used to cool homemade punch, and a leak of the sulfur-dioxide refrigerant had occurred that day. Apparently the sulfur dioxide had dissolved in the water being frozen into ice cubes, producing hydrogen sulfite which reacted with the cadmium to produce cadmium sulfite. As a result of this experience, the New York City Sanitary Code was amended in 1939 to prohibit the use of cadmium in utensils or apparatus intended to contain or be in contact with food or drink (Article 9, Section 145). Cadmium has become such a popular plating metal that more outbreaks of this sort may be expected, and this possibility should be kept in mind in the future in the investigation of explosive outbreaks of an afebrile, transient gastroenteritis.

Discussion

Dr Stanley W. Sayer, *Gouverneur, New York*.—Dr Perkins has presented a most complicated and difficult subject in a masterly manner. Public health workers in the field are constantly being brought in touch with gastrointestinal outbreaks, many of these casually coming to their attention when the outbreak is almost or even entirely over. There is such a variation in symptoms, particularly as far as severity is concerned, that recognition of an outbreak may depend upon the personality and attitude of mind of the physician or health officer.

It appears that church and other organization suppers are hazardous as far as gastrointestinal disease is concerned. This is probably due to the fact that facilities for thorough cooking and cleansing of utensils are not always available and also because of the fact that much of the food is prepared in the homes, some time in advance and under unsatisfactory conditions. In rural areas too, the water supply may be bad. Any public health control over this situation is difficult.

I should like to give further emphasis in relation to an outbreak of trichinosis due to the feeding of raw garbage and the entrails of slaughtered animals back in the same piggery. This is a most pernicious practice and apparently is not an uncommon procedure in smaller piggeries and slaughterhouses. When this practice is followed, a chance infestation of one animal will soon build up infection of every animal in the group.

In one particular outbreak, pork sausage appeared to be brown and well fried, yet the centers evidently were not reached by sufficient heat to

destroy the trichinae. Not long ago there occurred 2 cases of trichinosis from raw pork liver taken for treatment of anemia and prescribed by a doctor. The doctor failed to advise that raw pork liver might be dangerous.

Two outbreaks of considerable magnitude occurred during the Army maneuvers in northern New York last summer. We were informed by Medical Corps officers that diarrhea frequently followed careless washing of mess kits and that often the only thing that will make a man clean in this regard will be an attack of diarrhea. Although dirty mess kits were given as the cause of an epidemic of dysentery in a New York regiment, it was later found to be otherwise.

This regiment apparently did not like the chlorinated water provided and went to a poorly protected well nearby for drinking supply. An investigation carried out after the camp was evacuated indicated that the men had apparently washed their bodies and clothing beside the well. The diarrhea spread throughout the entire regiment and also affected a considerable number in the medical regiment which cared for these men. Bad water discipline was responsible for this Flexner type dysentery outbreak.

The second outbreak occurred among the personnel of the medical regiment of a midsouth

division of 300 men. They stopped enroute at a CCC camp overnight, this camp being located about 100 miles from their final destination. Sandwiches were prepared at this camp so that the men would have sufficient to eat until their camp could be set up and mess prepared.

Many of the sandwiches made were of egg and mayonnaise. The weather was warm and humid and the sandwiches were transported without refrigeration and eaten about fifteen hours after they had been prepared. Four hours later men were taken violently ill with nausea, vomiting, profuse diarrhea, abdominal pains, prostration, and dehydration. Some of the patients collapsed while walking about the grounds. Eighty were affected, most of them recovering within forty-eight hours. A few of them remained ill for several days.

It was found that one of the CCC boys who prepared the food had an infection in one of his hands which upon examination yielded *Staph aureus*. This was probably a staphylococcus toxin outbreak.

Although the three circumstances discussed were apparently traced to their source without too much difficulty, we are not so fortunate many times. It occurs so often that even after considerable time is spent in investigation the source and cause are unobtainable.

LABORATORY AIDS IN THE DIAGNOSIS AND CONTROL OF ENTERIC DISEASES

ALBERT H. HARRIS, M. D., and MARION B. COLEMAN, Albany, New York

FOR practical purposes, food-borne enteric diseases may be broadly classified into four groups: those induced by protozoa and helminths, by bacteria or their products, by chemical poisons, and those of unknown etiology.

Protozoa

One of the most important enteric diseases incited by a protozoan is amebiasis. The only ameba definitely known to be pathogenic for man is *Entamoeba histolytica*, although other species have been so considered by some authors.¹ Its rarity in the North should not cause us to forget that amebiasis exists here. Chronic carriers passing cysts in the feces may transmit the disease to others. Patients in the acute or subacute stage passing only motile forms, the so-called trophozoites, are not infectious for others, since the motile

amebas when ingested are killed by the gastric juices and fail to reach the intestine. By the examination of fresh stools and preparations stained with Heidenhain's hematoxylin, the laboratory worker can distinguish between *E. histolytica* and nonpathogenic forms and between motile forms and cysts. Various concentration methods aid in the finding of small numbers of cysts in the stools. Cultural methods are successfully employed in larger laboratories. The complement fixation test performed with the patient's serum is not in general use.² In this enteric disease more than in any other, it is important for the patient and the laboratory worker to be brought together, since only by the examination of absolutely fresh material can the laboratory diagnosis of amebiasis be satisfactorily undertaken.

Usually considered with *E. histolytica* are *Balantidium coli*, *Giardia lamblia*, and *Trichomonas intestinalis*. The clinical significance of these protozoa does not compare with that of *E. histolytica*, but they are said oc-

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, April 30, 1941.

From the Division of Laboratories and Research, New York State Department of Health.

casionally to incite dysentery. A laboratory equipped to diagnose amebiasis should be in a position to recognize these protozoa also.

Helminths

Infestation by most of the intestinal parasites can be determined by the discovery of the characteristic ova, larvae, adult worms, or worm segments in the stools, often accompanied by a moderate or marked eosinophilia. Most of the parasites are seen rather infrequently in upstate New York. Tapeworm infestation can easily be diagnosed if worm segments and ova are sought in the stools. A red blood count is helpful in suspected cases, since a primary type of anemia is not uncommon, especially when infestation is with the fish tapeworm, *Diphyllobothrium latum*. In the case of echinococcus cysts, a complement fixation test with the patient's serum, using cyst fluid as antigen, is employed as an aid in diagnosis in areas where this lesion is frequently encountered. A skin test is also done using material from the same source. At operation, the fluid can be examined and a fragment of the cyst wall may be removed for histologic study. The appearance is characteristic, especially when scolices are present.

Trichinosis is induced by the ingestion of encysted forms of *Trichinella spiralis*, lodged in infested pork that has been improperly cooked. Suspicious clinical symptoms coupled with the finding of leukocytosis and eosinophilia should lead one to submit for laboratory examination the pork product believed to be implicated. By means of digestion with pepsin, it is possible to release the encysted trichinellae from the muscle fibers and to collect them for examination at the bottom of a settling tube. The same result can be obtained by examining serial histologic sections of a sample of meat, but the method employing digestion is less time-consuming. The inoculation of rats with suspected material and the subsequent examination of the musculature by methods outlined above may demonstrate the presence of the encysted forms in infested meat when other methods fail. According to Schwartz^{2,4} of the United States Department of Agriculture, the examination of pork for *T. spiralis* in connection with routine inspection of meat would be too costly and would give a false sense of security. He recently expressed this opinion before the New York State Trichinosis Commission.⁵ The trichinellae can, in rare instances, be demonstrated in stools and even in

blood in the diarrheal stage of the infection. A biopsy specimen of muscle from a human case may be examined histologically, and at autopsy the larvae are most easily found in the muscle of the diaphragm. Reports, particularly from the U. S. Public Health Service, indicate that skin testing with an antigen prepared from this parasite may be helpful in the diagnosis of a suspected case. The antigen is not yet in common use, however. The skin testing of hogs has not been found to provide a reliable index of the presence or absence of the disease. The reliability of precipitin and complement fixation tests with the patient's serum is open to question.

Bacteria

The largest and most important group of enteric diseases is composed of those induced by bacteria or their products. Cholera has lost all but its historical importance for us. The isolation of the cholera vibrio from fresh stools and its identification by specific tests present no special problem for the experienced bacteriologist. It is well known, however, that the vibrio cannot always be found in the stools of clinical cases in an epidemic.

Typhoid fever has become relatively infrequent as a result of continued watchfulness on the part of health authorities and physicians and because of improvements in sanitation. In the diagnosis of the disease and in the control of the carrier state in a larger number of individuals, the laboratory plays an important role. It is well known that *B. typhosus* is often found in the blood during the first week of illness and can usually be readily cultivated by the ordinary blood-culture methods or by culturing the clot after the serum has been removed for use in the agglutination test. Typhoid bacilli in stools or urine are always significant, since they are found only in specimens from cases or carriers. There is evidence that healthy individuals may become transitory carriers and, therefore, it is particularly important that a person be declared a chronic carrier only when the typhoid bacillus has been found in the feces or urine for a considerable time.

When the bacteriologic examination cannot be undertaken promptly after collection, buffered 30 per cent glycerol solution provides a medium in which the recognized bacillary incitants of enteric disease and nonpathogenic species in feces and urine are maintained in a relatively stable ratio. Best results are obtained when feces approximately the size of a large pea are carefully suspended in the glyce-

erol solution. When urine is submitted the jar should be nearly filled. Usually, the sole focus of infection in a chronic carrier is the gallbladder. The examination of material obtained by duodenal drainage provides the only reliable basis for advocating cholecystectomy in an attempt to cure such a carrier. This type of examination is also important in the release of a carrier after cholecystectomy. The selective mediums now available make the isolation of bacillary incitants of enteric disease a less formidable task than heretofore.

Differentiation of strains of *B. typhosus* into types by determining their sensitivity to the lytic effect of various bacteriophages was first reported by Craige and Yen,^{6,7} of Toronto, in 1937. Lazarus,⁸ of Denver, was the first in the United States to report on the typing of a large number of strains. The procedure is such that it should be undertaken only in the larger laboratory where the volume of work justifies the maintenance of the bacteriophages and the standard cultures employed for purposes of control. The practical advantage to the epidemiologist of the typing of typhoid bacilli is obvious. Persons infected by a chronic carrier have always been found to harbor typhoid bacilli of the same type as those discharged in the feces of the carrier. Just as is the case with blood typing in medicolegal cases involving paternity, the finding of the homologous type of typhoid bacillus in the feces of a carrier believed to be responsible for a given case of typhoid fever does not positively incriminate him, but the finding of a heterologous type definitely relieves him of responsibility for the infection of that patient.

The value of the agglutination test as an aid in the diagnosis of typhoid fever has for many years depended upon the demonstration of two types of agglutinative properties in patients' serums—flagellar or floccular agglutination demonstrated with living or formalin-treated suspension of an actively motile strain of *B. typhosus*, and somatic or granular agglutination demonstrated with a living suspension of a nonmotile strain or an alcohol-treated suspension of either a motile or a nonmotile strain. Both types of clumping in a 1:80 or higher dilution are rarely observed in serums other than those from patients having typhoid fever, unless typhoid vaccine has been recently administered. Indeed, both floccular and granular agglutination in a high dilution of serum occurs rarely in recently vaccinated cases, but the fact

that febrile diseases other than typhoid may increase the agglutinating activity of the serum of recently vaccinated individuals calls for an accurate history and caution in evaluating the result of the test. Usually, floccular agglutination alone in a serum dilution of 1:80 or higher is induced by vaccination or is an indication of typhoid fever in the past or of an existing carrier condition. Granular agglutination in a 1:80 or greater dilution and little or none of the floccular type may occur in serums from patients having typhoid fever, but such findings are most commonly associated with infections with microorganisms antigenically related to *B. typhosus* and, thus, suggest the possibility of paratyphoid fever. When Felix and Pitt⁹ first described the Vi (virulence) antigen in typhoid bacilli, they not only established its antigenic individuality but also suggested that it was associated with the virulence of this species. We know now that virulence is not always imparted by the presence of this antigen. However, it is of significance that Vi agglutinative properties can be demonstrated in the serums from a high percentage of typhoid carriers and in few of those from non-carriers.^{10,11,12} This is a somatic antigen and is agglutinated in a granular manner. It is heat-labile, and active immunization against typhoid fever does not usually result in the development of Vi agglutinating activity in the serum. Thus, the presence of serologic activity against the Vi antigen takes on added significance.

Vaccination against typhoid fever with killed suspensions of *B. typhosus* was shown to be effective in the war of 1914 to 1918. Since paratyphoid fever induced by *B. paratyphosus* A is rare in New York State and since *B. paratyphosus* B infections are relatively uncommon, vaccine consisting of *B. typhosus* alone is now being dispensed by the Division of Laboratories and Research of the New York State Department of Health. Triple vaccine is being administered in the Army because of the possibility of the soldiers being stationed where paratyphoid fever is more common. Revaccination by the intradermal injection of 0.1 ml. of antityphoid vaccine at one- to two-year intervals has been found to yield high serologic activity against the bacillus as indicated by mouse protection tests.

The paratyphoid-enteritidis, or *Salmonella*, group is composed of seventy some species and others are constantly being recognized. The identification of members of this group

is often laborious and time-consuming. Their classification in the Kauffmann-White Schema^{13,14} is based upon the fact that slight differences in the antigenic structure of the cell bodies and flagella of individual types can be detected by agglutination in highly specific serums. Dr F. Kauffmann at the International Salmonella Center, Copenhagen, Denmark, has supplied small amounts of the necessary serums to a few laboratories in this country which have been designated Salmonella centers. One is located at Beth Israel Hospital in New York City and one in the Division of Laboratories and Research of the New York State Department of Health. From the standpoint of treatment, the final identification of strains in this group is of doubtful importance. However, as an aid to prognosis of the probable severity of the infection, typing of strains is helpful, since certain members of this group characteristically induce more violent gastrointestinal and systemic disturbances than others. To the epidemiologist, the identification of strains may be of the greatest aid in establishing a connection between cases of enteric disease and the presumptive source of infection. Some members of this group invade the blood stream, and hence the cultural examination of blood during the early stages of illness may be of value. The examination of feces and urine is subject to the same recommendations as in the case of typhoid fever. Some of the species in this group have been associated with localized infections, such as osteomyelitis and empyema, and have been isolated occasionally from sputum from patients having pneumonia¹⁵ and from spinal fluid from cases of meningitis. Agglutinative properties for the inciting microorganism are usually demonstrable in the patients' serums but, because of the large number of species in the group and their close antigenic relationship, agglutination is usually of little value as an aid in diagnosis.

Bacillary dysentery is as common in this state as amebic dysentery is uncommon. However, the differential diagnosis is of great importance, and the laboratory is in a position to confirm the clinical differentiation through a study of the stools. For evidence of bacillary dysentery, the examination of fresh stools is preferable but, if the specimen must be sent by mail, it should be suspended in buffered 30 per cent glycerol in salt solution. Hardy and his co-workers^{16, 17, 18} have published an excellent series of papers that link modern laboratory and epidemiologic

methods in the study of acute diarrheal diseases. They have made use of the method of rectal swabbing and direct plating on selective mediums for the isolation of dysentery bacilli.

Dysentery bacilli are rarely, if ever, found in blood or urine. The agglutination test with patients' serums is of little value because reactions are not ordinarily obtained sufficiently early in the disease to aid in diagnosis and because so many types of dysentery bacilli that vary in their antigenic properties are recognized. Fortunately, *B. dysenteriae* Shiga, the most virulent of the dysentery bacilli, is extremely uncommon in New York State. A large group of strains that ferment mannitol and are antigenically related is known as the Flexner group. Members of this group and also *B. dysenteriae* Sonne are common in this area. Although the Schmitz and Newcastle types are less common than the Flexner and Sonne, extensive outbreaks incited by them have occurred in institutions in New York State.^{17, 19, 20, 21}

Cases of severe enteric disease, usually occurring in children, in which the only significant microorganism appears to be an unidentified species of gram-negative bacillus have occurred frequently enough and with a sufficiently high mortality rate to command serious attention. The characteristics of this microorganism and the lesions induced by it have been described by McIver and Pike,²² Schleifstein and Coleman,²³ and Curphey.²⁴ Other species that have occasionally been thought to incite enteric disease are *B. morganii* No. 1, *B. alkalescens*, and *B. dispar*. These are also frequently found in feces from normal individuals, and their significance has not been established.

Certain food-borne diseases in which the incitant enters by way of the gastrointestinal tract have been omitted for the sake of brevity and because the appropriateness of their inclusion in this symposium on food-borne diseases of the gastrointestinal tract is open to question. I refer especially to undulant fever, milk-borne streptococcal infections, intestinal tuberculosis, and, just possibly, poliomyelitis.

Bacterial Toxins

Botulism is induced by the ingestion of bacterial toxins and, although comparatively rare, is of especial importance because of the high mortality rate. The attempted demonstration of the presence of botulinus

erol solution. When urine is submitted the jar should be nearly filled. Usually, the sole focus of infection in a chronic carrier is the gallbladder. The examination of material obtained by duodenal drainage provides the only reliable basis for advocating cholecystectomy in an attempt to cure such a carrier. This type of examination is also important in the release of a carrier after cholecystectomy. The selective mediums now available make the isolation of bacillary incitants of enteric disease a less formidable task than heretofore.

Differentiation of strains of *B. typhosus* into types by determining their sensitivity to the lytic effect of various bacteriophages was first reported by Craigie and Yen,^{6,7} of Toronto, in 1937. Lazarus,⁸ of Denver, was the first in the United States to report on the typing of a large number of strains. The procedure is such that it should be undertaken only in the larger laboratory where the volume of work justifies the maintenance of the bacteriophages and the standard cultures employed for purposes of control. The practical advantage to the epidemiologist of the typing of typhoid bacilli is obvious. Persons infected by a chronic carrier have always been found to harbor typhoid bacilli of the same type as those discharged in the feces of the carrier. Just as is the case with blood typing in medicolegal cases involving paternity, the finding of the homologous type of typhoid bacillus in the feces of a carrier believed to be responsible for a given case of typhoid fever does not positively incriminate him, but the finding of a heterologous type definitely relieves him of responsibility for the infection of that patient.

The value of the agglutination test as an aid in the diagnosis of typhoid fever has for many years depended upon the demonstration of two types of agglutinative properties in patients' serums—flagellar or floccular agglutination demonstrated with living or formalin-treated suspension of an actively motile strain of *B. typhosus*, and somatic or granular agglutination demonstrated with a living suspension of a nonmotile strain or an alcohol-treated suspension of either a motile or a nonmotile strain. Both types of clumping in a 1:80 or higher dilution are rarely observed in serums other than those from patients having typhoid fever, unless typhoid vaccine has been recently administered. Indeed, both floccular and granular agglutination in a high dilution of serum occurs rarely in recently vaccinated cases, but the fact

that febrile diseases other than typhoid may increase the agglutinating activity of the serum of recently vaccinated individuals calls for an accurate history and caution in evaluating the result of the test. Usually, floccular agglutination alone in a serum dilution of 1:80 or higher is induced by vaccination or is an indication of typhoid fever in the past or of an existing carrier condition. Granular agglutination in a 1:80 or greater dilution and little or none of the floccular type may occur in serums from patients having typhoid fever, but such findings are most commonly associated with infections with microorganisms antigenically related to *B. typhosus* and, thus, suggest the possibility of paratyphoid fever. When Felix and Pitt⁹ first described the Vi (virulence) antigen in typhoid bacilli, they not only established its antigenic individuality but also suggested that it was associated with the virulence of this species. We know now that virulence is not always imparted by the presence of this antigen. However, it is of significance that Vi agglutinative properties can be demonstrated in the serums from a high percentage of typhoid carriers and in few of those from non-carriers.^{10,11,12} This is a somatic antigen and is agglutinated in a granular manner. It is heat-labile, and active immunization against typhoid fever does not usually result in the development of Vi agglutinating activity in the serum. Thus, the presence of serologic activity against the Vi antigen takes on added significance.

Vaccination against typhoid fever with killed suspensions of *B. typhosus* was shown to be effective in the war of 1914 to 1918. Since paratyphoid fever induced by *B. paratyphosus* A is rare in New York State and since *B. paratyphosus* B infections are relatively uncommon, vaccine consisting of *B. typhosus* alone is now being dispensed by the Division of Laboratories and Research of the New York State Department of Health. Triple vaccine is being administered in the Army because of the possibility of the soldiers being stationed where paratyphoid fever is more common. Revaccination by the intradermal injection of 0.1 ml. of antityphoid vaccine at one- to two-year intervals has been found to yield high serologic activity against the bacillus as indicated by mouse protection tests.

The paratyphoid-enteritidis, or *Salmonella* group is composed of seventy some species and others are constantly being recognized. The identification of members of this group

Discussion

Dr Samuel Frant, *New York City*—It is manifestly impossible to discuss in detail a paper of such broad scope as the one just presented. The authors have given a concise review of the role of the laboratory and the part it plays in the investigation of enteric disorders. The opinions expressed agree with those held by the New York City Department of Health and may be taken as a fair statement of modern public health practice.

As laboratory methods become better developed, new fields of thought are opened up. I should like to discuss briefly on one such aspect of the role of the laboratory. You are no doubt well aware of the increased ease with which incitants of enteric disease can be demonstrated by the newer mediums, such as bismuth sulfite, desoxycholate citrate SS Agar, introduced by Difco, and tetrathionate broth. As a result of the use of these mediums, our department laboratory is reporting at least 100 per cent more positives than before.

The reporting of this increased number of positives in cases and contacts of typhoid fever has led to new situations and the raising of new problems.

1. Every case of typhoid fever reported in New York City is followed for one year after original termination. Stool specimens are obtained every three months in order to determine complete freedom from the carrier state in these recovered cases. An increasing number of individuals with positive specimens is now being found for the first time, as long as six months and nine months after clinical recovery and discharge from isolation by negative laboratory findings. There is evidence, therefore, that the carrier state following an attack of typhoid fever is probably much more common than was formerly realized.

2. In the investigation of every case of typhoid fever in New York City, every household contact is required to submit a stool specimen. We are now getting many positive isolations in well contacts to these cases. These contacts at no time have had typhoid fever, nor do they present any symptoms at the time of the positive specimens or subsequently. In many instances, after one or two weeks of having positive stools, these contacts clear up completely, and repeated examinations make it likely that they are probably not chronic carriers.

However, up to the present time the New York City Sanitary Code regulations require that any individuals with positive stools and no previous history of typhoid fever be put under legal restrictions as chronic typhoid carriers. Certainly, some modification of these regulations must be made to take care of this new situation. Other health authorities are having this same experience. No doubt from free discussion of this situation, procedures for the fair and proper treatment of such individuals will be evolved.

toxin in canned food is time-consuming and not worthwhile unless symptoms suggestive of botulism are present in individuals who have partaken of it. *Clostridium botulinum* or its toxin may be found in the patient's feces, and the toxin may be demonstrated in the blood by animal inoculation, providing antitoxin has not been administered. In any case, treatment must be initiated before results of the laboratory examination can be obtained. Food or feces are cultured anaerobically, and guinea pigs and mice are inoculated to demonstrate toxin. The animals develop muscular weakness and usually die of respiratory paralysis. Strains A, B, and E^{25,26} have been recognized, the products of which have been shown to be toxic for man. Specific antiserum that is effective against one type is ineffective against the others. Therapeutic serums for types A and B are available, a pool of the two being used when the type of the offending toxin is not known.

Other microorganisms are believed either to elaborate or to release, upon their dissolution, enterotoxins. Certain strains of staphylococci have been shown to be responsible for the formation of toxins during growth in many different types of foodstuffs. Many outbreaks of food poisoning, as illustrated by a recent report by Coughlin²⁷ of the New York State Department of Health, have been traced to cream-filled pastries in which enterotoxins of staphylococci were demonstrated. The ubiquitous nature of this microorganism always casts doubt on the significance of its presence, but finding it in large numbers in food that has been adequately refrigerated, after portions thought to have induced food poisoning were consumed, is circumstantial evidence that the strain is enterotoxic. The laborious laboratory procedures necessary to demonstrate such enterotoxins scarcely seem justified. If this information is desired in connection with legal proceedings in damage suits, the work should be undertaken in a laboratory where the examinations can be performed under conditions fulfilling the requirements of a court of law and where appropriate charges can be made.

Other Incitants

A large number of chemicals is capable of inducing gastroenteritis, but the problem of their demonstration and identification by laboratory methods is a toxicologic one for the chemist.

There are enteric diseases associated with

vitamin deficiency and allergy, as well as metabolic and other functional disturbances, that can scarcely be called food-borne diseases. There are also diseases of unknown etiology, some of which may be food-borne, but the diagnostic laboratory furnishes relatively little help except in a negative sense in their diagnosis or control. Examples are epidemic diarrhea of the newborn, discussed by Frant and Abramson,²⁸ also so-called intestinal grip, ulcerative colitis, regional ileitis, and appendicitis.

Finally, the role of the laboratory in assisting the sanitary engineer and the health officer in the prevention of food-borne diseases must not be overlooked. By laboratory examinations in connection with restaurant sanitation, by the search for microorganisms of the coliform group and other evidence of pollution of water, and by bacterial counts in milk and the phosphatase test to determine completeness of pasteurization, the laboratory forms part of the bulwark against the outbreak of epidemics of enteric disease.

Laboratory Service in New York State

The importance of cooperation between the physician and the laboratory deserves emphasis. The physician may contribute to the insuring of optimum results by the selection of the proper outfit for each specimen and by care in the collection of material, as well as by providing pertinent information on the history forms that are provided for this purpose. Clinical data are often essential to the laboratory director for evaluating results obtained with a given specimen, for determining what additional tests should be performed, and for suggesting to the physician further laboratory procedures that might be advisable. Failure to receive adequate clinical information is one of the greatest difficulties a laboratory has to face.

In New York State the major part of the laboratory work under discussion is performed in local approved laboratories under high standards of efficiency. The central laboratory, by collaborating with them, is in a position to assist with special procedures, such as the identification of unusual strains and the evaluation of new methods.

be evacuated. Not infrequently, the patient feels much better as a result of the first washing-out of the stomach, and the second dosage of soda water seldom requires the coercion that the first did. Often the patient retains most of the second dose. In this case he benefits decidedly from the treatment, since he is now ready to start absorbing water. In many instances the patient does not vomit the soda water originally given him but retains it comfortably. In a short period of time, he feels decidedly better.

It is good policy to evacuate the stomach early in the treatment of any case of food-borne disease of the gastrointestinal tract. There may be times when the stomach tube is necessary for this purpose, especially if there is evidence of the ingestion of chemicals and particularly of poisons.

As soon as the stomach has been evacuated, treatment should be directed to the bowels. Even though the patient has diarrhea, a dose of saline cathartic should be administered. The saline cathartic is preferred because it produces a profuse watery discharge from the bowels with a minimum of cramping and pain. Also, if the patient is suffering from an infective disease such as bacillary dysentery, the addition of Epsom salts to his regimen is particularly valuable. In all cases the dose should be adequate and should be administered promptly.

(2) *Adequate Supportive Measures*—These should be instituted promptly and should include infusions with glucose in normal saline. As a rule, 2½ to 5 per cent solutions of glucose in normal saline are adequate and, according to the condition of the patient, these should be given in amounts from 1,000 to 3,000 cc in twenty-four hours. Whenever possible, it is desirable to use large quantities of fluid by intravenous infusion rather than by clysis, which causes much more distress to the patient. If fluids are given by infusion, it is important that they should be administered slowly, at a rate of not more than 30 to 40 drops per minute.

Blood transfusions are most valuable as supportive measures and should be used frequently. Indeed, they provide one of the most important supportive methods at the disposal of the physician because they serve to give the patient adequate red blood corpuscles as well as proteins.

Heat in various forms constitutes a simple but timely method of supporting the patient. Hot water bottles and warm, light blankets are especially helpful in this connection. Hot

drinks are of great importance if the patient appears to be in collapse. Strong coffee or tea is to be recommended.

Attention to food intake and to fluid elimination is important. As a rule, the diet on the first day or two following the onset of an acute intestinal disease should be light, preferably liquid. It should be wholesome and should contain adequate quantities of proteins and carbohydrates. Fruit juices may include grapefruit, orange, and lemon. A tablespoonful of sugar may be added to the juice of a freshly squeezed lemon, and the mixture may be served to the patient with a spoon. This gives the patient something tart, while the granules of sugar provide something that he can crunch. Fruit juices provide adequate vitamins and carbohydrates, which after all are most important. As a general rule, milk is not well tolerated in the early stages of an acute infection. Since there is a marked difference in the reaction of individual patients to milk, experience with each one must serve as guide to the amount of milk prescribed for the patient's diet. Boiled rice and macaroni may be used for a day or two. Care should be taken to avoid depletion of the patient's protein and vitamin reserves when planning his diet. As rapidly as possible, the patient should be given a more solid diet, including high-protein and high-vitamin foods.

The Treatment of Irritative Lesions of the Gastrointestinal Tract

Irritative lesions of the gastrointestinal tract are generally caused by chemical agents. Chemical irritants have to be dealt with vigorously, and treatment must be directed to whichever drug is suspected.

It is impossible in the scope of this paper to discuss all the chemical agents that may be related to food-borne diseases. The most important, however, is alcohol, which is one of the most common chemical agents responsible for irritative lesions of the gastrointestinal tract. Alcoholism may be either acute or chronic. In the acute stages it is a relatively simple matter to cause evacuation of the gastrointestinal tract and then to give various stimulants such as coffee or tea. Within a short time the patient is on his feet again. On the other hand, when alcohol has been used over a considerable period of time, definite systemic changes take place. While these may be related to the body as a whole, they are chiefly due to the failure of vitamin metabolism of the body. This is especially true of vitamin B₁. There may be a decrease in the

THE TREATMENT OF FOOD-BORNE DISEASES OF THE GASTROINTESTINAL TRACT

Z BERCOVITZ, M D , New York City

THE treatment of diseases of the gastrointestinal tract calls for a careful case history and accurate diagnosis of the condition present. At the same time, the patient's general condition should be evaluated and all necessary measures should be taken to build up or maintain his strength. With few exceptions there is no specific therapy for the diseases of the gastrointestinal tract. Treatment, therefore, includes general systemic therapeutic principles. Indeed, the first consideration of the physician at all times is the welfare of the patient, and consequently his attention should not necessarily be concentrated upon bacteria, protozoa, or chemical agent. The physician has to treat patients, not diseases.

The differential diagnosis of the various food-borne diseases of the gastrointestinal tract includes

- (1) Irritative lesions
 - (a) Chemical
 - (b) Alcoholic
 - (c) Dietary indiscretions
- (2) Bacillary diseases of bacterial origin
 - (a) Bacillary dysentery
 - (b) Typhoid-paratyphoid group
 - (c) Salmonella group
- (3) Protozoan infections
 - (a) *Endamoeba histolytica*
 - (b) *Giardia lamblia*
 - (c) *Balantidium coli*

E. histolytica and *Bal. coli* are known to be related to diarrheal conditions, but the evidence in the case of *G. lamblia* is not clear. Most authorities generally consider other protozoan infections of academic interest only, since they are not definitely related to disease.

- (4) Helminthic infestations
 - (a) Trichinosis
 - (b) Bilharzia
- (5) Allergic conditions
- (6) Chronic ulcerative colitis

Fundamental Regimen

The fundamental regimen in the treatment of every case of food-borne disease of the

gastrointestinal tract is relatively simple but must be applied energetically and with a good measure of common sense. It must be remembered that whenever a patient has developed a disease of the gastrointestinal tract there is fundamentally a disturbed physiology of both the stomach and the intestines, including the small bowel as well as the colon. This disturbed physiology may be evidenced by nausea and vomiting, and by distention of the abdomen accompanied by gas, rumbling, and gurgling. Changes in biliary function may become evident and there may be diarrhea. When there is frequent evacuation of the bowels, there may be watery, pea-soup-like stools, which may be of foul odor and may even contain blood or mucus. All these symptoms may be transient or persistent. The fluids of the body are depleted rapidly if these symptoms appear, especially if there is nausea and vomiting with the diarrhea. At the same time there is rapid loss of all the vitamins. Thus, in a matter of hours some patients may be in a serious general condition as a result of a simple dietary upset. In those unfortunate individuals who may be allergic to various foods and whose upset is caused by increased sensitivity to certain articles of diet, generalized symptoms may appear immediately. On the other hand, infection with bacillary dysentery may result in a sudden onset of acute symptoms, which may become exceedingly serious within a few hours. Regardless of the cause of the disease, the fundamental principles of treatment include the following:

(1) *Adequate Elimination*—This should be prompt and should include both the stomach and the intestinal tract. A simple method of evacuating the stomach is to have the patient drink in rapid succession three large tumblers of tepid water, to each of which a heaping teaspoonful of baking soda has been added. In all probability a large amount of mucus or other irritating material is present in the stomach if the patient is nauseated or vomits. If he vomits immediately after drinking the tepid water and soda, his stomach is emptied of whatever mucus and other irritative material may be present there. If this results, the treatment should be repeated immediately so that all the contents of the stomach will

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, April 30, 1941.

From the Department of Medicine, New York Post-Graduate Medical School and Hospital, Second (Cornell) Medical Division, Bellevue Hospital and Department of Medicine, Cornell University.

of chronic ulcerative colitis. For that reason both conditions may be considered together.

Dosage with Epsom salts has been considered almost specific for acute bacillary dysentery. Used for over a century by physicians experienced in the tropics and in the Orient, the crystals of Epsom salts are administered morning and evening during the first day in a tablespoonful dose to which a small quantity of water is added. On the second day, a tablespoonful of Epsom salts should be given and, depending upon the preference of the physician, may be given as a single dose in the morning or in divided doses throughout the day. It is better to give it as a single dose in the morning because the patient will have several fluid evacuations from the bowels before the day is over, and by nightfall he should be improved. Within forty-eight to seventy-two hours it will be noticed that the patient is having less straining and tenesmus, and the character of the bowel discharge will have changed from a small amount of sticky blood, mucus, and pus to a more copious fluid fecal character. By the third day there will be some evidence of soft, watery fecal discharge which, within another twenty-four hours, will become soft and mushy in character. In the meantime the patient's general condition will be markedly improved, he will be less toxic and the outlook generally will be more encouraging.

Glucose infusions as outlined under general symptomatic treatment are of vital importance at this point. It is necessary to give 2,000 to 3,000 cc of 5 per cent glucose by intravenous infusion in twenty-four hours. In addition, 500 cc of whole blood, either by the direct or indirect method, may be given every day or every other day, depending upon the patient's general condition. The physician should not be misled by a relatively high erythrocyte count because this may represent the result of concentration resulting from dehydration. The patient's general condition is the best guide in the matter of blood transfusions and glucose infusions. It has been noted frequently that there is a more watery discharge from the bowel when glucose infusions are given. This should, however, not alarm the attending physician.

Rest, both physical and mental, is of great importance in the treatment of a patient with an acute bacillary dysentery infection or with chronic ulcerative colitis. The patient is worried and he feels ill, his judgment is not accurate and he is easily irritated by little things. He is soon considered "nervous,"

and frequently nervousness of one sort or another is blamed for his symptoms when, in reality, he is quite naturally "nervous" as the result of bowel movements twenty to thirty times a day. A patient of this sort is benefited most by the administration of adequate sedatives, especially of bromides. Habit-forming drugs, such as codeine and morphine, are to be most scrupulously avoided. The barbiturate group may be used cautiously, but the drugs that should be used are the triple bromides, to which chloral hydrate may be added if necessary. A favored prescription is

R	
Triple bromide	30 cc
Chloral hydrate	20 cc
Elixir of phenobarbital q s	120 cc
M Sig	One teaspoon q 4 h

For some individuals, it may be sufficient to give 15 or 30 grains of the effervescent triple bromides dissolved in an adequate amount of water. This dose, taken every four hours, is usually sufficient to keep the patient at rest, even though he has to evacuate the bowels. Between evacuations he is able to obtain badly needed rest.

Serum therapy in bacillary dysentery offers a subject for discussion. When introduced a number of years ago, it was generally considered that serum therapy offered one of the most adequate methods of approach to the difficult problem of treating this disease. It was soon found, however, that satisfactory results were obtained only when the dosage was sufficient and when it was administered early. It is generally considered that the serum must be polyvalent in character and administered in large quantities within the first week of the disease. Eighty to 100 cc of polyvalent serum must be given every day for two or three days if satisfactory results are to be obtained. Unfortunately, this dosage is usually followed by severe serum sickness, which may be more difficult to treat than the original disease. For this reason, many who have had to deal with large numbers of cases of bacillary dysentery prefer to depend on the Epsom salts treatment rather than on polyvalent serum.

Chemotherapy has also been explored in the search for a suitable method of treating bacillary dysentery. Within the past few years attention has been focused upon many new chemicals, and in some fields the results have been most gratifying. Drugs of the sulfanilamide group, including not only sulfanilamide but also neoprontosil, sulfapyri-

free hydrochloric acid of the stomach that results in a coincident depletion of the body reserves of vitamin C as well as vitamin B. These cause bleeding from the gastrointestinal tract and also diarrhea, with the development of mucus. Other systemic evidences of vitamin B and vitamin C deficiencies which have to be treated intensively may develop. In the case of vitamin B deficiency, it is urgent that the patient should receive adequate amounts of both thiamine chloride and the whole vitamin B complex. To insure absorption, these should be administered parenterally. Vitamin C is also available for parenteral administration. The dosage of thiamine chloride should be adequate. It should include a minimum of 60 to 120 mg daily for the first week, after which it may be reduced to about 50 mg a day for the next two weeks. One of the vitamin B complex preparations may be given by intramuscular injections. As a rule, 1 or 2 cc are administered daily over a period of weeks. Unrefined preparations of liver extract, administered by injections, constitute the best means of giving the patient the whole vitamin B complex in its natural state.

Irritative lesions resulting from food indiscretions should be treated as acute irritative lesions. Usually the simple evacuation of the gastrointestinal tract both by mouth and by bowel is sufficient.

Diseases Caused by Bacterial Agents

It is not definitely known just what part many of the bacteria of the gastrointestinal tract play in relation to disease conditions, and so consideration will here be limited to those bacteria that are known to cause disease of the gastrointestinal tract.

The bacillary dysentery group of organisms is related to some of the most difficult and severe disease conditions of the gastrointestinal tract. Bacillary dysentery is an acute disease caused by one of the group of organisms included in the Flexner, Shiga, or Sonne groups. Invasions of the gastrointestinal tract by these organisms are characterized by such sudden and dramatic onset that within a few hours the patient is transferred from a well and strong individual into one who is fighting for his life. Symptoms begin with diarrhea with blood, mucus, pus, straining, tenesmus, and toxemia. The patient is rapidly dehydrated and feverish and within a few hours may be having such constant evacuations of the bowels that he is literally "glued to the bedpan." When the physician is confronted with

a patient suffering from these severe symptoms, he should immediately examine microscopically a specimen of the bowel discharges. He should also have an immediate bacteriologic examination made of the stools. The unfortunate victim of bacillary dysentery strains to eliminate as little as a teaspoonful or a tablespoonful of blood, mucus, and pus, which are mixed together into a sticky substance that adheres to the bedpan. If a drop of this discharge is placed immediately upon a slide, covered with a coverslip, and examined microscopically, it will be noticed that there is a myriad of cells of all shapes and descriptions. Under the high dry power of the microscope, specimens prepared in this manner reveal the presence of many round to oval cells, containing as a rule three rather prominent nuclei which mark them as polymorphonuclear leukocytes. These should not be confused with cysts of *E. histolytica*. A differential diagnosis of bacillary dysentery, chronic ulcerative colitis, and amebic dysentery on the basis of the cellular exudates of bowel discharges is made in the work of Bercovitz.¹⁻⁴ In order to make sure of the nature of the exudate, the physician should take another drop of the mucus, which may be mixed with a drop of Löffler's methylene blue, covered with a coverslip, and examined as a wet coverslip preparation. The methylene blue promptly stains the cells of tissue origin. It is possible by this method to demonstrate adequately the polymorphonuclear leukocytes and the denuded, toxic, epithelial cells. When these cells are found in profusion, a preliminary presumptive diagnosis of bacillary dysentery may be made. Appropriate therapy can then be instituted at once. Bacillary dysentery is a disease involving the mucosa of the entire large bowel, which may have single or multiple ulcers as well as diffuse necrosis of the bowel wall accompanied by sloughing. The degenerated, denuded, epithelial cells seen in the microscopic examination of a methylene blue coverslip preparation are the result of this diffuse necrosis of the bowel mucosa. When this condition is present, it must be treated promptly and adequately. Even under the best conditions of therapy it may develop into chronic ulcerative colitis. In fact, many physicians believe that a certain percentage of all cases of chronic ulcerative colitis is secondary to, or results from, an acute attack of bacillary dysentery. The fundamental treatment of bacillary dysentery does not differ radically from the fundamental regimen required in the treatment

clumps of epithelial cells, endothelial cells, and macrophages, are mistaken for trophozoites of *E. histolytica*. One of the most common mistakes is to consider polymorphonuclear leukocytes as cysts of ameba. Furthermore, in spite of the finding of trophozoites of amebas in a bowel discharge, if the patient has not improved within seventy-two hours, digital examination and proctoscopy should be performed, since a bowel malignancy may be present.

Anayodin in enteric-coated tablets, given by mouth, presents one of the most valuable forms of therapy in both the acute and chronic amebic dysentery. The dose in the adult is a total of 100 tablets administered as follows: 3 tablets, three times daily, until the 100 have been consumed. If there is an acute involvement of the bowel, there will be irritation resulting from the anayodin, which contains 25 per cent iodine. This is not a serious condition and usually takes care of itself at the end of the treatment. In some instances, however, the anayodin causes an increase in the frequency of the bowel movements. If this condition becomes too severe, the dosage of anayodin may be reduced temporarily. The use of compounds containing arsenic is to be avoided because of the danger of arsenic poisoning. Many of these preparations have been widely advertised as "nontoxic," but the danger of arsenic poisoning still lurks.

Bal coli infections should be treated in the same way as those caused by *E. histolytica*.

One of the advances that has been made in recent years is in the treatment of *G. lamblia*. Atabrin is now considered almost specific for *G. lamblia* infections. The dose of atabrin and the method of administration are as follows: given in tablets by mouth, each tablet contains 0.1 Gm. of atabrin, 1 tablet is given three times daily after meals for a total of seven days. By that time the infection has usually cleared up. Re-examination of the stools and of specimens by duodenal drainage has failed to reveal further infections with this parasite. A single course of treatment is sufficient in most cases.

Diseases Caused by Helminths

Trichinosis is the most common helminth disease of the gastrointestinal tract caused by food. It results from the ingestion of inadequately cooked pork. There may or may not be gastrointestinal symptoms but, if there are, they are usually of a mild nature and consist of transient diarrhea or a certain amount of nausea and vomiting. Following these

symptoms, there may be some swelling of the face with or without conjunctival hemorrhages, fever, and the development of leukocytosis with an increase in the number of eosinophils. The diagnosis is usually made by intradermal testing, by the precipitin reaction, and by muscle biopsy.

There is no specific treatment for trichinosis infection. All the known chemotherapeutic agents have been tested and found wanting. The disease follows a course of about three weeks' duration, with a decline in temperature by lysis and a gradual return of the patient to health and strength. The use of toxic drugs or poisonous chemicals are definitely contraindicated in trichinosis. The patient needs to be supported, not poisoned. Treatment calls for saline purge, glucose infusions, rest in bed, and adequate high-protein diet.

Gastrointestinal Allergy

There are apparently definite instances of a specific allergic reaction of the gastrointestinal tract as a result of the ingestion of certain foods. As a rule the patient knows what foods may cause this condition. When the patient gives a history that suggests food sensitivity, the physician must investigate the problem thoroughly. It may be necessary to perform various tests or even to do studies with an elimination diet.

Summary and Conclusions

Food-borne diseases of the gastrointestinal tract may be caused by various conditions, including dietary indiscretions, chemical agents, and alcohol. They may be bacterial in origin, while still others may be protozoan or helminthic in origin. Whatever the cause may be, certain fundamental principles in therapy are required. These include:

1. Proper elimination both from the stomach and the bowel.
2. Supportive measures, such as infusions and blood transfusions.
3. Absolute rest, both physical and mental, preferably with the aid of nonhabit-forming drugs.
4. Diet should be high in proteins, total calories, and vitamins.
5. Specific therapy where indicated, e.g., emetine in amebic infections, etc.

When all is said and done, the physician must use common sense in the care of his patient and must remember that his first problem is to maintain the general health of his patient. Treatment of the particular gastrointestinal disease is, of course, impor-

dine, sulfathiazole and, more recently, sulfaguanidine, have been noticed. All these drugs have had their advocates, for some of which spectacular results are claimed. But it is important to stress that before claim is made for the potency of any drug its use should be carefully controlled in a large number of patients over a sufficient period of time. Thus, before the drug is accepted, a stool culture should be made and bacterial counts determined. In addition, a urine examination and complete blood count should be recorded. Following the administration of the drug, the blood level of the drug should be determined. This is relatively simple for a laboratory equipped to deal with ordinary chemical methods, because the sulfone group of drugs can be identified and measured in the blood readily. It is important to make daily readings of blood levels of these drugs as well as daily urine determinations and daily complete blood counts. A daily stool culture and bacterial count in the stool are also vital. At the first sign of toxic symptoms, such as changes in the blood count and the presence of blood, proteins, or crystals in the urine, the drug should be discontinued. Before any positive statement can be made of the efficacy of a chemical preparation, an adequate number of cases should be studied over a long period of time. Until a perfect chemotherapeutic agent has been developed, the wise conservative course to follow is the fundamental regimen already outlined for the treatment of gastrointestinal diseases.

Typhoid fever is one of the most important disease conditions that we have to deal with. At one time it was considered a disease in which the patient had to be starved, but now an adequate diet has been worked out which represents one of the greatest advances yet made in the therapy of typhoid fever. It is now generally accepted that full diet has had much to do with the reduction in the mortality rate of typhoid fever in the past few years. With a better understanding of the diet required by the typhoid fever patient, it has been possible to lessen the severity of his symptoms. Wasting and anemia are never as marked as they used to be. Since the introduction of the high caloric diet, adequately supplemented by the known vitamins and proteins, there has been a marked decrease in the incidence of hemorrhage and perforations. Treatment today is diametrically opposite to that of a decade ago. The problem today is to give the patient as much food as possible. Four thousand calories a day are considered

the optimum, although it is seldom possible to get the patient to take more than 3,000 calories. Together with the high caloric diet, the physician should follow the general fundamental regimen so that the patient's fluid balance is well maintained. The hygiene of the mouth is of great importance. Antipyretics are to be avoided, but tepid, sponge baths may be used as well as alcohol rubs. If the patient is seen before there is danger of perforation, a mild gentle saline laxative may be used, but great caution should be exercised in this connection. Under the adequate dietary regimen of today, the problem of constipation, tympanites, and distention of the abdomen is not so serious as it used to be.

Diseases Caused by Protozoa

The commonest diseases caused by protozoa are the infections resulting from invasions of *E. histolytica* and *Bal. coli*. These two protozoa are known to be pathogenic. *G. lamblia* is another parasite that is frequently found. Although it is not regarded as a pathogenic protozoa, every physician experienced in parasitology has seen instances in which the elimination of the *G. lamblia* from the patient's system has been attended by improvement in his general condition.

Infections with *E. histolytica* are divided into acute and chronic stages, and treatment must be given accordingly. Treatment of the acute condition, in which trophozoites of *E. histolytica* are found in the bowel discharges, includes the use of emetic hydrochloride by subcutaneous injections. This drug should never be given intravenously because of the danger of toxic action upon the heart muscle. The dosage is 0.03 Gm ($\frac{1}{2}$ grain) subcutaneously morning and evening (1 grain daily), until a total of 7 grains has been administered. The blood pressure and pulse should be recorded before the injection of each dose. If there is a marked change in the blood pressure or pulse rate at any time, the administration of the subsequent dose should be omitted. In the course of treatment of acute amebic dysentery the most dramatic improvement should occur within forty-eight to seventy-two hours. If there has been no definite change in the patient's condition by the end of the fourth day, careful re-evaluation of the entire case should be made. If possible, stool specimens should be re-examined not only with fresh preparations but also with Lugol's solution and with methylene blue so that a careful study can be made of the cellular exudates. Frequently, cells of tissue origin, such as

abscess. In addition, it is essential to give a subsequent course of anayodin, even where amebiasis are not demonstrated in the feces. The hepatic involvement always originates in the colon.

Data concerning the use of the specifics for helminthic infestations are available in various texts. I will make only one general observation. In the treatment of metazoal infestations, it must be remembered, in contrast with protozoan and bacterial infections, that the parasites do not multiply in the host once the infestations are established. Furthermore, they have

a limited life span. Consequently, a therapeutic result short of complete elimination of the parasites is not, as with bacteria, a total failure. If 90 or 95 per cent of the parasites are eliminated, the body will usually be able to cope with the few remaining organisms until such time as they die a natural death. Thus, for example, if after an anthelmintic is given for hookworm a few ova are still found in the feces, it is not essential to repeat therapy immediately. The potential toxicity of the therapy may be more serious than the disturbance caused by the few remaining parasites.

TO STRENGTHEN THE NATION BY BETTER DIETS

A campaign aimed at correcting the faulty diets of the American people by educating them through the various mediums of public information such as newspapers, magazines, and radio on the proper selection of food is being planned as a part of the national defense program, Dr. Russell M. Wilder, Rochester, Minnesota, reports in the March-April issue of *War Medicine*, published by the American Medical Association, Chicago, in cooperation with the National Research Council, Washington, D. C.

"Famine has always contributed to defeat of armies and subjugation of nations," he says. "This long has been recognized, but in the past it was mistakenly thought that famine could be prevented if only the supply of food sufficed. The newer knowledge teaches that the nutritive quality of the foods supplied is of the utmost importance.

He says that a report, "based on food purchases by large samples of the urban and rural populations of the United States shows that no more than a quarter of the families of the United States have diets that can be rated as good, that little more than a third have diets rating as fair, and that another third or more have diets classed as poor. I have heard expressions of skepticism about these conclusions, but support for them comes from the findings of many independent dietary surveys in which the foods actually eaten have been measured and the persons examined by physicians.

"The committee has presented detailed proposals for organizing the communities of the nation in a wide nutritional education campaign to bring into active participation patriotic groups, labor and religious bodies, fraternal orders, and organizations of churches, of women, and of young persons.

"The committee also proposes stimulation of research involving combined nutritional and social studies of selected communities to determine what articles of food are selected and what are rejected by food folkways and to ascertain by physical tests the effect of such traditional habits on the organism.

"The Committee on Food and Nutrition of the National Research Council, through a subcommittee, is concerning itself with problems of procurement of concentrated sources of nutrients, such as powdered milk, yeast, vitamin concentrates, and synthetic vitamins. Enormous supplies of them will be required here or abroad, whether the war comes to American shores or not."

Another subcommittee, in cooperation with the Committee on Industrial Medicine of the Committee on Health and Medicine, has to deal with the special nutritional requirements of industrial centers.

"One cannot put into heavy industry a man who has been subsisting on a deficient diet and expect efficiency unless one first builds him back into an efficient human machine," the author says.

"PTOMAINE POISONING" A MYTH

"Ptomaine poisoning doesn't exist," Dr. Dorothy V. Whipple, Washington, D. C., declares in the April issue of *Hygeia, The Health Magazine*. She explains that illness caused by eating food that is not wholesome is not due to the presence of ptomaines in the food and should more accurately be termed food poisoning than ptomaine poisoning.

"Ptomaine," the physician continues, "is a word for substances that form in decomposing foods. There are many different compounds that come under the general term ptomaines, but they all have in common the property of being made by bacteria out of decomposing

protein. Some of these ptomaines have distinct odors and tastes, which are largely responsible for the characteristic flavor of putrid food. However, unbelievable as it may seem to many people, the ptomaines in such food, even when the food is eaten in large quantities, produce no ill effects in the human body."

Dr. Whipple lists as the cause of food poisoning: (1) The food eaten may itself be naturally poisonous, (2) bacteria may have been made poisonous substances in once wholesome food, (3) chemical poisons may have been accidentally introduced into the food, or (4) bacteria may have been allowed to grow in the food.

tant, but its success depends in no small measure upon the physician's ability to maintain the general condition of the patient.

Discussion

Dr. Howard B. Shookhoff, *New York City*—It is a great pleasure to discuss this comprehensive paper presented by Dr. Bercovitz. I shall confine my remarks primarily to the animal parasites that involve the gastrointestinal tract.

These infections and infestations will assume more and more prominence in the field of medical practice in the months to come. The ever increasing movement of persons among the countries of this hemisphere, as a result of the present political conditions, will lead inevitably to the appearance of a greater number of cases of so-called tropical diseases outside the usual endemic areas. The practicing physician must become increasingly aware, when gastrointestinal symptoms present themselves, of the possibility of encountering conditions such as amebiasis, giardiasis, or strongyloidiasis, remembering that diarrhea is not the only indication for an examination of the stool. The great importance of detecting these conditions lies in the fact that effective specific therapy is available in almost every instance.

I must pause here to underline Dr. Bercovitz's remarks to the effect that we must treat the patient as well as the parasite. The very availability of specific chemical agents tends to make us forget measures that are nonspecific but important. Virtually every pathogenic invasion of the gastrointestinal tract entails systemic disturbances. If we neglect these, we not only fail to get a complete therapeutic result but we increase the possibility of toxic effects from the specifics employed. In addition, it must be emphasized that specifics such as emetine and founadin are not, in themselves, parasiticides in the concentrations occurring in the host but require the cooperation of the resistance mechanisms of the host. Where systemic disturbances are neglected, these mechanisms cannot act with optimal effect.

It is of great importance that the specific therapy of diseases caused by animal parasites be intelligently administered. I say this because the symptoms of such diseases are often ill-defined and are frequently found not alone but in combination with other diseases. Often, one cannot say with certainty that the clinical picture presented is due to the parasite encountered until relief of symptoms has been produced by a

course of specific therapy. In other words, the therapy constitutes a diagnostic procedure as well.

The most important animal parasite found in this climate is *E. histolytica*. Yet, despite the Chicago epidemic of 1933, amebiasis is still one of the forgotten diseases. Many still do not appreciate its frequency or the fact that it may be responsible for a wide variety of clinical pictures. True dysentery occurs actually in a minority of cases only. While the diagnosis of the condition requires considerable technical experience, the principles of therapy should be more generally known. I should like to amplify a little Dr. Bercovitz's remarks. Anayodin is the drug of choice. Personally, I prefer to start with 3 tablets the first day, 6 the second, and then 9 a day thereafter. Whenever there is active diarrhea, fever or other evidence of systemic involvement, or doubt as to the diagnosis, a course of emetine should be given first. But emetine alone should never be relied upon to produce a lasting cure. In cases with marked involvement of the lower colon or in cases that fail to respond to the oral administration of the drug, it is desirable to secure a greater concentration of the agent in the colon by the use of retention enemas. These consist of 200 cc. of a 2½ per cent solution, given daily for a period of ten days. A cleansing enema of sodium bicarbonate solution precedes the retention enema.

For resistant cases the combination of these retention enemas with the oral administration of emetine bismuth iodide is advisable. It is worth pointing out in passing that iodism is not seen with anayodin therapy.

Liver abscess, the most important complication of amebiasis, is usually regarded as a surgical condition. Actually, recent writings such as those of Manson-Bahr point out that the majority of cases respond either to emetine alone or to the combination of closed aspiration and emetine. I have recently reviewed 15 cases of amebiasis of the liver treated at the Presbyterian Hospital in New York City during the past ten years. The findings are extremely instructive. In only 1 case was surgical drainage employed. This terminated fatally, probably because the etiology was not recognized and no emetine was administered. Two cases were successfully treated with two or three aspirations plus the administration of emetine hydrochloride. The remaining 12 cases responded to one or more courses of emetine without requiring aspiration, even where the clinical picture pointed to abscess formation.

Thus, when the diagnosis of amebiasis of the liver is suspected, a course of emetine is always indicated, even though real evidence of abscess formation is apparent. Where an exploratory laparotomy reveals a liver abscess, a course of emetine should always be given, even though amebas are not found in the stools or abscess contents—as is often the case in amebic liver

played a significant role in American military medicine

In turning now to the present war situation there is no reason to believe that gastrointestinal problems will not loom large in our mobilization effort no matter whether this will be consummated in our own country or on foreign soil. It must be understood that our entire military policy is directed to the creation of effective fighting field forces, so that we must always think in terms of combat conditions. In this connection we are fortunate in having available the recent experience of the British Army. In an article published in December, 1940, Payne and Newman² report that early in the war it was noticed that indigestion appeared to present the biggest medical problem among the sick invalided back to England from the British Expeditionary Force in France, and the Royal College of Physicians was asked to investigate the matter.

The results of the investigation up to the time of publication of this preliminary report are summarized as follows: (1) Eighty-nine per cent of the cases investigated proved to be gross organic disease, there was little evidence of minor dyspepsia. (2) Almost all of the organic lesions found in the cases investigated were ulcers, and the majority of ulcers were duodenal. (3) Ninety-two per cent of the ulcers had been present before the war started, and only 8 per cent appeared to have originated after enrollment in the army. (4) In about 40 per cent of the cases the onset of the ulcer occurred before the age of 25. (5) A check on the type of physical examination received by men who later developed ulcers or a recurrence of former ulcers showed that a small number of them had been examined rather hastily and incompletely but that the majority had received careful attention before being admitted to the army. However, few had been asked specifically concerning previous gastrointestinal disease by the army examiners. Some men had obvious scars that might have disclosed their conditions had the examinations been more searching in this respect.

From present indications it seems quite possible that this experience of the British may well forecast our own situation and that among other forms of preparedness in this regard we should not neglect the continued development and maintenance of a strong section of gastroenterology within the Medical Department of our Army.

Gastroenterology in the American Army Today

Historical—The utilization of gastroenterologists in the United States Army dates back to World War days when, under the direction of Col Seale Harris in 1917, the Surgeon General's Office set about the task of assigning a specialist in this field to each of the thirty-three base hospitals in this country. Although the authority for this type of assignment was discontinued before the end of the war, the idea apparently bore fruit, for special gastrointestinal services were continued in the organization of the fixed general hospitals of the Army. Such services have functioned successfully in each of the four large hospitals caring for general medical cases—namely, Walter Reed, Letterman, William Beaumont, and Fort Sam Houston, where approximately 10 per cent of the beds were set aside for alimentary cases.

The final step in the utilization of gastroenterologists and the recognition of this specialty as an integral part of the medical service of general hospitals took place on July 25, 1940. On this date the War Department issued a Table of Organization for the General Hospital, known as No 8-507. According to this directive, the medical service includes, in addition to 1 lieutenant-colonel as chief and 1 major as assistant chief, 6 majors as chiefs of the following sections: gastroenterology, neuropsychiatry, general medical, cardiovascular, communicable disease, and (sick) officers. It also includes 9 captains as ward officers and internists with training in tuberculosis, neuropsychiatry, allergy, dermatology, metabolism, gastroenterology, cardiology, neurology, and contagious diseases and, finally, 4 lieutenants as ward and assistant ward officers. In this way gastroenterology is assigned its proper place among the chief subdivisions of internal medicine and is allotted its proper quota of trained medical officers.

Personnel—The officer personnel for the section of gastroenterology can now be secured from rosters of Regular Army or Reserve officers already qualified in this work. If additional officers are required to meet the needs of the present emergency, they may be secured from the lists of available civilian physicians now being assembled by the American Medical Association from the responses to the questionnaire recently distributed. It may here be noted that the American Gastroenterological Association has

ROLE OF GASTROENTEROLOGY IN AMERICAN MILITARY MEDICINE

JOHN L. KANTOR, M D , New York City

THE role played by diseases of the digestive tract in American military history is as old as the country itself, the Continental Army having suffered heavily from typhoid fever* and dysentery during the Revolutionary War. Available statistics for the War of 1812 showed that dysentery and diarrhea probably led all other diseases. Following this conflict, a work was published on gastric physiology entitled *Experiments and Observations on the Gastric Juice*, (1833) which became one of the classics of our literature. The fact that this remarkable contribution was made by a medical officer, Dr William Beaumont, while on duty at an isolated frontier post of the United States Army makes it a source of enduring pride to American military medicine.

In the Mexican War dysentery, yellow fever, and malaria were the chief disabilities, whereas in the Civil War diarrhea and dysentery were the most common causes of mortality from disease and, following tuberculosis, the most important cause of discharge for disability in the Union forces. The intestinal fluxes produced over 1,500,000 casualties among the white troops in the northern armies, the annual admission rate per 1,000 being 8.76 and the death rate being 10.37. The total deaths in the Federal armies alone were over 57,000 or the equivalent of about four of our modern streamlined infantry divisions.

Following the Civil War, Woodward's classic volume appeared on the "alvine fluxes" as a part of the monumental *Medical and Surgical History of the War of the Rebellion* (1870-1875).

In the Spanish War the admission rate for diarrhea, dysentery, and intestinal diseases was 402, but the death rate per 1,000 had decreased from the Civil War level to 1.9. During and following the Spanish War and the Philippine Insurrection, the Medical Department of the Army made additional important contributions to the control of digestive disorders. Much, although not all, of this work

was accomplished by the appointment of specially qualified officers and their organization into boards for the study of special diseases.² One need only mention the names of Walter Reed and F. F. Russell in connection with the study and prophylaxis of typhoid fever, R. P. Strong in animal parasites, D. F. Craig, R. P. Strong, and W. E. Musgrave in the diagnosis and treatment of bacillary and amebic dysentery, Bailey K. Ashford in the discovery of the role of ankylostomiasis in the production of Puerto Rican anemia, and E. B. Vedder, W. P. Chamberlain, and James M. Phalen in the study and control of beriberi in our Philippine Scouts. It is a matter of pride to us all that many of these studies had not only local and military value but worldwide and general usefulness as well.

During the World War the admission rate for the diarrheal diseases was as low as 34 per 1,000 and the death rate 0.08 per 1,000. These figures for the American troops are probably the result of favorable environment since it should not be forgotten that British troops, stationed in the Dardanelles, had an admission rate of 254 and a death rate of 6.9 per 1,000 for dysenteric affections.

Turning to the military establishment in time of peace we find that according to the latest annual report of the Surgeon General (for 1939), the international class, designated "diseases of the digestive system," constituted the most common cause of admission, the rate for 1938 being 115.9. In that year these diseases stood third as a cause of death and of noneffectiveness.

During the recent First Army Maneuvers held in the northern part of New York State in 1939 and 1940, diseases of the digestive system led all other medical conditions admitted to the First Evacuation Hospital serving these troops. In 1939 alimentary diseases constituted about one-third of all medical cases, whereas in 1940 they constituted three-fifths.

The unusual proportion in 1940 was due to an epidemic of bacillary dysentery encountered during the last maneuvers. From the above brief review it seems reasonable to conclude that from the earliest times to the present, in peace as in war, digestive diseases have

Chairman's address: Section on Gastroenterology and Proctology, Annual Meeting of the Medical Society of the State of New York, Buffalo, April 30, 1941.

* Although the "jail fever" of that period is usually considered typhus, much of it according to Ashburn¹ was in reality typhoid.

played a significant role in American military medicine

In turning now to the present war situation there is no reason to believe that gastrointestinal problems will not loom large in our mobilization effort no matter whether this will be consummated in our own country or on foreign soil. It must be understood that our entire military policy is directed to the creation of effective fighting field forces, so that we must always think in terms of combat conditions. Such services have functioned successfully in each of the four large hospitals caring for general medical cases—namely, Walter Reed, Letterman, William Beaumont, and Fort Sam Houston, where approximately 10 per cent of the beds were set aside for alimentary cases.

The final step in the utilization of gastroenterologists and the recognition of this specialty as an integral part of the medical service of general hospitals took place on July 25, 1940. On this date the War Department issued a Table of Organization for the General Hospital, known as No. 8-507. According to this directive, the medical service includes, in addition to 1 lieutenant-colonel as chief and 1 major as assistant chief, 6 majors as chiefs of the following sections: gastroenterology, neuropsychiatry, general medical, cardiovascular, communicable disease, and (sick) officers. It also includes 9 captains as ward officers and internists with training in tuberculosis, neuropsychiatry, allergy, dermatology, metabolism, gastroenterology, cardiology, neurology, and contagious diseases and, finally, 4 lieutenants as ward and assistant ward officers. In this way gastroenterology is assigned its proper place among the chief subdivisions of internal medicine and is allotted its proper quota of trained medical officers.

Personnel—The officer personnel for the section of gastroenterology can now be secured from rosters of Regular Army or Reserve officers already qualified in this work. If additional officers are required to meet the needs of the present emergency, they may be secured from the lists of available civilian physicians now being assembled by the American Medical Association from the responses to the questionnaire recently distributed. It may here be noted that the American Gastroenterological Association has

appointed a Committee on Military Preparedness, which is now actively helping in the selection of qualified specialists

The enlarged enlisted and nursing personnel required for the Section of Gastroenterology will be secured from the usual sources—namely, the operation of the Selective Service Act in the case of the former and the American Red Cross in the case of the latter

Relation to Other Services—Close cooperation with other hospital services is necessary for both diagnosis and treatment. Among the most important contacts of the gastroenterologic service are those with the roentgen service, the laboratory service, the surgical service, the dental service, and the dietetic service. Also important are relations with the representatives of the Sanitary Corps in regard to problems of epidemiology, parasitology and waste disposal, and with the Veterinary Corps in regard to inspection of foods of animal origin.

Research Possibilities—The military surgeon must be prepared to go anywhere and face any problem. If war comes, no man can tell what part of the world will constitute our theater of operations and no one can foretell the nature of the special problems that will undoubtedly arise. However, experience has already taught us that certain questions will probably press for an early answer. Among these, in my opinion, are the following pertaining to digestive diseases:

What are the best measures for the prevention, control, and treatment of the bacillary dysenteries? Although much work has already been done in this field, it still appears desirable to try some of the recommended procedures in a large-scale manner.

What is the best way for the Army to utilize the services of individuals who give a history of peptic ulcer? Many such persons, including doctors, are known to be competent in their respective fields. Should they be rejected categorically, should they be accepted conditionally and for limited duty, or should they be assigned to full duty if symptom-free? Data of prognostic importance which can help answer some of these questions must already be available in our own Army records. The experience of the British, previously referred to, should be useful in arriving at a decision. Similarly, what should

be done about individuals who have undergone gastroenterostomy or gastric resection?

How can modern knowledge of vitamins be utilized for the improvement of the Army ration? Some suggestive work has already been done in this direction.⁵

How may the services of dietitians be utilized not only for the preparation of invalid diets but possibly for the improvement of feeding throughout the Army?

As has been stated elsewhere,⁶ the remarkable control of material and the ability to follow up cases that obtains in the military establishment are the envy of civilian practitioners of medicine. Such facilities readily lend themselves to special investigations and, with the improved organization now contemplated, one may reasonably look forward to the writing of another brilliant chapter in gastroenterology by the Medical Department of the United States Army.

Summary

1 Diseases of the digestive system have always played an important role in war as well as in peace, in the Army as well as in the civilian community.

2 The Medical Department of the United States Army has made noteworthy contributions to the field of gastroenterology.

3 The Medical Department of the United States Army has officially recognized the importance of the specialty of gastroenterology by creating sections of gastroenterology as integral parts of the medical service in the latest Table of Organization for the General Hospital.

4 The almost ideal control of clinical material that obtains in the United States Army lends itself admirably to the study and solution of practical problems in diseases of the digestive system.

THE PRESENT STATUS OF VITAMINS IN NERVOUS HEALTH AND DISEASE

HERMAN WORTIS, M D , and NORMAN JOLLIFFE, M D , New York City

SINCE the review three years ago¹ on the role of vitamins in nervous health and disease, no significant clinical advances relative to the effects of vitamins A, C, and D have been reported. The present publication is, therefore, limited to vitamin B₁ (thiamin), nicotinic acid, vitamin B₆ (pyridoxine), and vitamin E (alpha tocopherol).

Vitamin B₁ (Thiamin)

Neurasthenic Syndrome—Tension and irritable weakness states, frequently alluded to as neurasthenia and nervous exhaustion, are manifested in complaints of fatigability, weakness and exhaustibility, head pressures, poor sleep, irritability, feeling of tenseness, inappetence, various aches and pains, subjectively poor memory, and difficulty with concentration. Additional complaints referable to the bowels, heart, skin, and genitourinary apparatus are not uncommon. The etiology of this condition is not clear, but it is generally thought to be one of the more constitutionally determined of the minor psychiatric reaction types. Various etiologies have been suggested, but none satisfactorily explains the picture. Freud himself felt that neurasthenia was the result of current physical factors and suggested that it was the direct physical result of excessive masturbation.² As the various hormones were isolated, each in turn was held responsible. In this vitamin era similar indictments are being made.

With a diet poor in vitamin B₁, Jolliffe and his co-workers³ were able to produce a neurasthenic syndrome in 4 out of 5 experimental subjects. Their subjects (interns) complained of fatigue, lassitude, anorexia, precordial pain, burning of the feet, dyspnea on exertion, muscle cramps, and palpitation. The objective signs observed were skin hyperesthesia in a sock distribution, changes in the electrocardiogram, and calf muscle tenderness. Symptoms were observed as early as the fourth day and objective signs as early as the fifth day, although 1 subject developed no definite symptoms or objective signs in thirty days

with a diet estimated to contain only 62 per cent of his vitamin B₁ requirement.

The addition of thiamin alone to the experimental diet caused all symptoms to disappear within three days, and the objective signs within six days.

It is interesting that McLester⁴ had previously noted that many of the pellagra patients seen at the Hillman Hospital in Birmingham were considered neurasthenics before the objective signs of pellagra became manifest. It is now well recognized that few cases of pellagra depend exclusively on a deficiency of nicotinic acid and that there is an additional deficiency of thiamin in most of these cases. He suggested that many of the nervous and mental symptoms of pellagra depend primarily on a lack of sufficient thiamin in the dietary regimen.

In 1940 the carefully controlled study of Williams and his co-workers⁵ apparently established the fact that a syndrome resembling neurasthenia could be produced by a diet deficient in thiamin. Their otherwise excellent study suffers from the fact that they utilized as experimental subjects 5 formerly psychotic individuals (3 cases of dementia praecox, 1 of psychosis with polymyositis, and 1 of paranoid psychosis) and 1 psychoneurotic. Since somatic complaints of the type listed in neurasthenia are common in such patients, their results must be accepted with reservations. The problem is additionally complicated by the fact that similar syndromes have been reported as cured by nicotinic acid,⁶ Vitamin B₆,⁷ and vitamin E.⁸ Furthermore, it should be kept in mind that the clinical picture of this syndrome is extremely varied, that many such pictures occur in apparently well-nourished individuals, and that these symptoms frequently respond to psychotherapy.

Therefore, it should not be inferred that all neurasthenia is based on thiamin or other nutritional deficiency. It does, however, seem fairly certain that a syndrome possessing many of the characteristics of the ill-defined neurasthenic syndrome can be produced by nutritional deficiency. We emphasize the need to isolate this group from neurasthenic syndromes of other etiology.

Peripheral Neuropathy—The peripheral

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, April 30, 1941.

From the Medical Service of the Psychiatric Division, Bellevue Hospital and the Departments of Psychiatry and Medicine, New York University College of Medicine.

neuropathy occurring in the alcohol addict is now generally accepted to be the result of a nutritional deficiency and, more particularly, to be related to a deficiency of thiamin^{9,10}. This concept receives new support from the experimental pathologic work of Swank,¹¹ Street,¹² and their co-workers. Furthermore, Bueding and Wortis^{13,14} have been able to demonstrate an elevation of blood and spinal fluid pyruvate in all cases of alcoholism with peripheral neuropathy. Since Peters¹⁵ has already shown that thiamin is concerned in the catabolism of carbohydrate at the pyruvic acid stage, this finding constitutes additional evidence for the metabolic etiology of this type of peripheral neuropathy.

The brain is dependent for its normal functioning on a carbohydrate substrate,¹⁶ an adequate supply of oxygen,¹⁷ and various enzyme and coenzyme systems.¹⁸ Among the more important of these latter are thiamin, nicotinic acid, and riboflavin. Since all of these substances are of great importance in the catabolism of carbohydrate, it is conceivable that a deficiency in any one of them may interfere with proper brain functioning by interfering with the proper utilization of dextrose, the essential foodstuff of the brain. Therefore, it is pertinent that we have never seen a case of acute peripheral neuropathy that did not simultaneously show some evidence of cortical dysfunction. Whether or not the spinal cord, which also utilizes carbohydrate¹⁹ as its main foodstuff, is similarly involved cannot always be determined. Experimental evidence is plentiful to show that the dorsal columns of the spinal cord are frequently involved in chronic alcoholism^{11,12} (with its associated nutritional disturbances). Since the portions of the peripheral nerve involved in this type of neuropathy are those eventually carried in the dorsal columns (touch, vibration, position sense), it is often difficult to determine whether or not myelopathy is present. Wortis, Stein, and Jolliffe²⁰ have demonstrated that it is the large myelinated fibers carrying these sense modalities which suffer first and most severely in this type of peripheral neuropathy. Finally, patients with so-called irreversible peripheral neuropathy frequently show rather marked improvement if a diet rich in other nutritional factors is added to the thiamin.¹⁵

Particular mention must be made of a paper by Meklejohn²¹ who doubts that this type of polyneuropathy is due to a deficiency of thiamin. He points out that most of the earlier writers merely suggested that "nutri-

tional" polyneuropathy was caused by deficiency of the hypothetical antineuritic vitamin and that it should not be construed to mean that the authors believed "nutritional" polyneuropathy to be due to a deficiency of the pure chemical substance thiamin—a therapeutic agent unavailable to them at the time. His objections have been answered point for point by Jolliffe.²² But this does not imply that the subject is a closed matter.

Our knowledge of normal nerve metabolism is by no means complete, and as additional light is shed on these other factors it may be that certain changes now considered irreversible will prove to be completely reversible. It seems probable that, in certain cases at any rate, factors additional to thiamin are necessary to insure the complete regeneration of the diseased peripheral nerves accompanying nutritional deficiency. There still remains a definite group in which the changes have apparently advanced to the irreversible stage, and vitamin therapy is of little help.

Previous reports^{23,1} that the peripheral neuropathy accompanying pellagra was improved by thiamin or cocarboxylase have been confirmed.²⁴

Of a total of 422 ambulatory diabetic patients examined by Fein, Ralli, and Jolliffe,²⁵ 9 (2.1 per cent) fulfilled the criteria for the diagnosis of peripheral neuropathy resulting from vitamin B₁ deficiency. In these 9 subjects there were no abnormal findings other than peripheral neuropathy and no other clinically evident vitamin deficiencies. The estimated vitamin/calorie ratio in these cases did not, however, support the presence of a vitamin B₁ deficiency. The authors therefore suggested that the presence of arteriosclerosis (all their patients were elderly) may necessitate a higher concentration of thiamin in the tissues to insure that adequate amounts reach the nerves. Hausman²⁶ has recently observed 3 cases of peripheral neuropathy in insulin-treated diabetic patients. The resulting increase in carbohydrate utilization requires additional thiamin to insure its breakdown, and in susceptible individuals a deficiency may result. The importance of this mechanism in the cases reported by Fein and his co-workers is doubtful, since all of their cases occurred in elderly patients rather than in the young severe diabetic patients. As a result of their uniformly excellent therapeutic results, the authors conclude that "the symmetrical peripheral neuropathy beginning first in, and involving primarily, the lower extremities of patients having diabetes mellitus responds to

thiamin hydrochloride, and in our opinion is due to vitamin B₁ deficiency."

Two additional reports have appeared indicating that vitamin B₁ may be of use in multiple sclerosis²⁷ and chorea.²⁸ Our own observations fail to confirm these findings, and this point of view is further confirmed in an excellent paper by Robie.²⁹ Moore's suggestion that the nicotinic acid acted as a vasodilator and increased the blood supply in such cases is interesting, but his case reports are not convincing.

A well-controlled study led Rose³⁰ to conclude that thiamin was of no benefit in trigeminal neuralgia, a finding previously noted by us and, since, repeatedly confirmed.

The indiscriminate use of vitamins in cases of toxic and infectious neuritis continues. Results in such cases are difficult to evaluate, and conclusions cannot be drawn at this time.

Himwich and his co-workers,³¹ studying the brain metabolism in 7 patients with pellagra uncomplicated by other deficiency diseases noted that the brain oxygen A-V difference was 6.16 vols per cent as compared to a normal of 7.43 vols per cent. Since studies of brain blood flow were not done, this difference may not be statistically significant. In 8 individuals who had pellagra complicated by beriberi, however, a marked depression of the oxygen A-V difference was observed, with an average value of 4.69 vols per cent. This difference may be caused either by a blood flow increased 60 per cent above the normal or by a diminished cerebral metabolism. The latter possibility is regarded as more likely. The decreased cerebral metabolism in pellagra complicated by beriberi may be due to lack of one vitamin or to a polyavitaminosis. Nonetheless, these observations seem to offer an explanation for the cortical changes that accompany these nutritional disturbances and that we have observed as an invariable accompaniment of "nutritional" peripheral neuropathy.

Encephalopathia Alcoholica—With regard to the alcoholic psychoses, the modern trend is away from the older assumption of a direct toxic action of alcohol on the nervous system and is more in favor of a metabolic, or more specifically an avitaminotic, disturbance caused by the chronic ingestion of alcohol.³² This is contributed to by the following factors:³³ (1) The diet of alcoholic patients is deficient in vitamins. (2) The increase in total metabolism which occurs in alcoholic states, and particularly in delirium tremens, requires a larger supply of vitamins. As a

result, relative or absolute deficiencies may appear which might not otherwise be present. (3) Alcoholic patients have impaired gastrointestinal absorption because of associated gastritis and hepatitis. As a result they do not completely absorb even the small amounts of food they do eat. (4) The substitution of vitamin-free alcohol for vitamin-containing foods. (5) The increased vitamin requirement in consequence of the additional calories furnished by alcohol.

Delirium Tremens—The literature contains many articles indicating that thiamin chloride³⁴ and nicotinic acid³⁵ are either specific or have considerable value in the treatment of delirium tremens. On the other hand, Spies and his co-workers³⁶ reported negative results with nicotinic acid, and Rosenbaum³⁷ noted no essential difference whether vitamin B₁ or nicotinic acid is given or omitted in the routine therapy of these cases. As a matter of fact, they reported the experimental production of an attack of delirium tremens in a person suffering from chronic alcoholism who was given huge doses of thiamin chloride and nicotinic acid but was allowed to drink about 1 quart of whiskey per day. The delirium began thirteen days after this regimen was started.

Our published results^{25,33,40} indicate clearly that deficiency of thiamin and nicotinic acid is not specific in the causation of delirium tremens or administration of these vitamins in the treatment of this disease. We do, however, believe that delirium tremens is a factor of considerable importance in producing other nutritional disturbances of the nervous system (Wernicke's syndrome, nicotinic acid deficiency encephalopathy, peripheral neuropathy). As noted above, the marked increase in psychomotor activity which accompanies these delirious states so raises the metabolic requirements that clinically latent deficiency states may become manifest. We have, however, seen too many cases of delirium tremens recover entirely on saline and fluids to include nicotinic acid or thiamin in the specific treatment of this condition. We believe that thiamin and nicotinic acid, as well as the entire B complex, should be given to all patients with delirium in order to prevent the development of peripheral neuropathy, Wernicke's syndrome, and nicotinic acid deficiency encephalopathy and, perhaps, to prevent the development of as yet unknown types of encephalopathy related to nutritional disturbances. Delirium tremens may, of course, be related to some as yet un-

discovered or untried vitamin, but the evidence for thiamin and nicotinic acid is meager indeed.

Wernicke's Syndrome—In 1881 Karl Wernicke,⁴¹ on the basis of 3 cases studied carefully during life and at autopsy, delineated a clinical syndrome characterized by clouding of consciousness, varying ophthalmoplegias, and ataxia. The author did not indict alcohol as the causative agent but suggested that various toxins, including alcohol, might produce the clinicopathologic picture. Nonetheless, most subsequent cases were reported in inebriates, and alcohol gradually came to be accepted as the etiologic basis of this condition. As a matter of fact, Wernicke's original case did not occur in an alcoholic patient.

The patient was a 20-year-old seamstress who was admitted to the Charité following a suicidal attempt with sulfuric acid. She left the hospital after several days, but soon thereafter persistent and intractable vomiting set in, probably as a result of pyloric stenosis. The vomiting continued, and after one month she became stuporous and developed ophthalmoplegia and ataxia. In addition, there was moderate swelling of the optic disks with associated retinal hemorrhages. Her condition gradually became worse, and she died one week after the onset of this complication. Wernicke's other 2 cases, however, did occur in alcoholic patients who were admitted in delirium. The essential pathology was described by Wernicke and has been further elaborated by others. In general, the lesions are confined to the periventricular gray matter and are characterized by small foci of degeneration and varicose deformities of the blood vessels. There is subacute necrosis of the adjoining parenchyma, and small petechial hemorrhages are frequently, but not always, found throughout the lesions.

In addition to innumerable reported cases in inebriates, a review of the literature reveals some 40 cases described in nonalcoholic individuals. These latter cases are usually associated with gastrointestinal disorders or carcinomas accompanied by cachexia and vomiting. Many of these authors suggested a metabolic etiology, but opinion regarding the nutritional origin of the Wernicke syndrome was not crystallized until 1938, when Alexander and his co-workers⁴² were able to produce this syndrome in pigeons fed on a thiamin-deficient diet. They could not reproduce the disease in pigeons fed thiamin, even though they were deprived of all other vitamins or of any one other vitamin for a period of over six

months. In 1940 Alexander⁴² amplified his original report and showed conclusively that the lesions of Wernicke's polioencephalopathy occurring in man, and the disease he produced experimentally in pigeons deficient in vitamin B₁, were identical in their topographic distribution and in their morphologic and histologic characteristics.

We⁴³ have recently reported our clinical findings in 27 cases. Of the total, 3 occurred in nonalcoholic patients (2 depressed patients who refused to eat, and 1 case of pulmonary tuberculosis with associated vomiting). The other 24 occurred in chronic alcoholic individuals.

Our results may be summarized as follows:

1. The syndrome as originally described by Wernicke is probably a combination of several nutritional deficiencies affecting the nervous system and need not necessarily be complete in any case. It is, of course, possible that the exact syndrome that Alexander has reproduced experimentally in pigeons may occur in uncomplicated fashion in man, but beyond the fact that the patient would have ophthalmoplegia the other symptoms would be difficult to evaluate from a purely clinicopathologic point of view.

2. Our results indicate that (a) the ophthalmoplegia is a thiamin deficiency, (b) The clouding of consciousness may be related to anything that interferes with proper brain metabolism. Among the known offenders are lack of carbohydrate, lack of oxygen, lack of thiamin, nicotinic acid, and riboflavin, and probably lack of many other substances now under investigation, (c) The ataxia is difficult to evaluate, and its response to therapy has not as yet been worked out.

3. Other deficiency syndromes (pellagra, nicotinic acid deficiency encephalopathy, riboflavin deficiency) may, and do, superimpose themselves on the more usual Wernicke picture, and these require specific treatment.

4. The ophthalmoplegia is invariably preceded or accompanied by peripheral neuropathy. Since the latter results from a thiamin deficiency, this finding tends to confirm Alexander's thesis that they have a common etiology and that the polioencephalopathic changes represent a more complete deficiency in thiamin.

5. Delirium with its marked increase in psychomotor activity and, hence, in total metabolism usually precedes the development of this syndrome. In this type of case, the early administration of thiamin will prevent the development of ophthalmoplegia.

6 All cases that received adequate vitamin therapy recovered. In the recovered cases the development of a Korsakoff syndrome is the rule. The latter does not show a consistent response to thiamin therapy as has frequently been claimed.

Korsakoff's Syndrome—This psychosis consists in deficient power of retention for recent events, with a tendency to confabulate, and disorientation for time, place, and person. It may or may not be associated with peripheral neuropathy. Although most usually associated with chronic alcoholism, it is seen in conjunction with many other conditions (head injury, arteriosclerosis, subarachnoid bleeding, toxic and drug psychosis, etc.). Because of its frequent association with peripheral neuropathy, lack of thiamin has long been suspected, and several confirmatory reports have already appeared^{45,46}. These reports are probably the result of premature optimism. Our experience with the syndrome convinces us that not all cases of this type are the result of nutritional disturbances and that even where such disturbances do exist the role of thiamin is still to be determined. We have previously reported¹ that the confabulatory features of an acute delirium usually clear while the patient is receiving a diet deficient in vitamin B. In the more chronic cases, Bowman and his associates⁴⁷ have shown that thiamin seems to help in the recovery of these patients but is nowise specific. In these latter cases it may be argued that the changes have become irreversible. At any rate, the role of thiamin in the genesis and treatment of the Korsakoff syndrome still remains to be determined, and the evidence at hand is not at all convincing.

Regarding the manifestations of "encephalopathia alcoholica," we believe that each such patient should be labeled as to the clinical signs or syndromes presented, the response of these phenomena to specific therapeutic agents recorded, and, finally, the metabolic and pathologic changes correlated with the clinical picture found during life. It is our belief that studies of this type will undoubtedly lead to a much better understanding of the nutritional and metabolic disorders that interfere with the functional economy of the nervous system.

Nicotinic Acid

Pellagra was first described by a Spanish physician, Gaspar Casal⁴⁸ in 1735, but his observations were not published until 1762, three years after his death. The first published report appeared in the French literature

in 1755, but the author, formerly physician to the French ambassador at the Spanish court, freely acknowledges his debt to Casal. States of mania, depression, and confusion are described as accompanying the "mal de la rosa," and their severity and chronicity are stressed. "Without doubt these are produced by metastasis to the brain of the acrid and malign humours which produced this malady," He cites the example of a woman who, "during one of the melancholy deliriums so frequent in this disease, had a great desire to feed herself from cow's butter, for which she spent all her property, and she was cured."

Almost immediately following the discovery of the value of nicotinic acid in the treatment of certain manifestations of human pellagra, a number of articles⁴⁹⁻⁵² appeared concerning its usefulness in the treatment of the cerebral disorders seen in persons suffering with pellagra. Spies and his co-workers⁴⁹ state that pellagra patients are noted for the multiplicity of their complaints, among which are many that are usually classified as neurasthenic. The most common of these symptoms are fatigue, insomnia, anorexia, vertigo, burning sensations in various parts of the body, numbness, palpitation, nervousness, a feeling of unrest and anxiety, headache, forgetfulness, apprehension, and distractibility. The conduct of the person with pellagra is normal, but he feels incapable of physical or mental effort even though he may be ambulatory. They noted that the "neurotic" symptoms showed a prompt response to nicotinic acid therapy. Probably of greater significance than the relief of "neurotic" symptoms following nicotinic acid is their observation that these symptoms return when, without the patient's knowledge, nicotinic acid is withdrawn and another medicament of similar appearance is substituted for it.

The more obvious mental manifestations of pellagra are the various organic psychoses that complete the diagnostic triad of diarrhea, dermatitis, and dementia. Perhaps the most common is that in which loss of memory, disorientation, confusion, and confabulation are present. There are also types in which excitement, depression, mania, and delirium may occur. In our experience a paranoid condition is common in pellagra as in many other organic psychiatric pictures. Spies and his associates⁴⁹ report that all their psychotic patients recovered, but the psychosis in most of their cases was only of one to two weeks' duration. We can confirm these findings with our own experiences at Bellevue

Hospital We would, however, emphasize the fact that careful psychiatric examination reveals that these patients are frequently left with residual organic memory defects. In the psychoses of longer duration associated with pellagra, the response to nicotinic acid is certainly not spectacular, and specific therapy may not help at all. This does not mean that a lack of nicotinic acid was not important in the genesis of the mental picture. It does, however, point out the fact that these metabolic disturbances finally proceed to structural changes. When this latter stage is reached, the process may become irreversible. It must similarly be emphasized that many of the acute excitements and deliriums associated with pellagra frequently clear up without nicotinic acid therapy. Finally, pellagra patients are usually lacking in other factors contained in the well-balanced diet and probably necessary for normal brain metabolism. It is therefore suggested that adequate amounts of other vitamins be given to pellagra patients with encephalopathic manifestations in order to insure maximal therapeutic results.

Cleckley, Sydenstricker, and Geeslin⁵³ have reported on 19 stuporous patients who showed a remarkable response to nicotinic acid therapy. They concluded that hebetic grading into profound stupor may be the only sign of severe acute pellagra and that therapeutic trial of nicotinic acid is justifiable as the only method at present available for the diagnosis of such cases.

Jolliffe, Bowman, Rosenblum, and Fein⁵⁴ have reported 150 cases of an "encephalopathic syndrome," heretofore almost invariably fatal, which they believe is caused by nicotinic acid deficiency. This syndrome may occur as the only manifestation of a deficiency disease or it may occur in association with pellagra, polyneuritis due to vitamin B₁ deficiency, or the ophthalmoplegia associated with Wernicke's disease. The clinical picture of this syndrome is more or less well defined and is characterized by clouding of consciousness, cogwheel rigidities of the extremities, and uncontrollable sucking and grasping reflexes. To be excluded are the encephalopathic manifestations of groping, grasping, and sucking which may occur during the course of delirium tremens, infectious diseases with delirium, expanding intracranial lesions, advanced cerebral arteriosclerosis, and other diseases. Jolliffe also notes that some of the cases previously described by Spies,⁴⁹ Matthews,⁵⁰ Sydenstricker,⁵¹ and Cleckley,⁵² and

their co-workers may have belonged to this group.

Since not all of the cases showing this syndrome presented the usual skin and mouth lesions associated with pellagra, it was assumed that this syndrome represents an acute *complete* nicotinic acid deficiency, which develops so rapidly that the structural changes in the skin and mouth, characteristic of pellagra, do not have time to occur. Patients manifesting this syndrome and treated by hydration or hydration plus thiamin hydrochloride almost invariably died (95 per cent), patients treated by hydration plus concentrates rich in the vitamin B complex showed a marked drop in mortality (50 per cent), but when these patients were treated by hydration plus nicotinic acid, the mortality fell to 15 per cent.

Vitamin B₆

A specific syndrome in man attributable to a deficiency of vitamin B₆, or pyridoxine has as yet not been reported. Therapeutic effects have, however, been noted in several diseases of the nervous system, although its true position in the field of nerve tissue metabolism still remains to be determined.

Paralysis Agitans—Jolliffe⁵⁵ administered pyridoxine in doses of 50 to 100 mg intravenously either daily or every other day to 15 patients with paralysis agitans. Four showed subjective and definite objective improvement. Two additional patients were subjectively improved. Of the 11 patients who showed no objective improvement, 10 had suffered disability for more than three years, and 5 of these gave a history of encephalitis.

Spies⁵⁶ soon thereafter confirmed this observation and reported the dramatic improvement, particularly of the tremor, in patients having postencephalitic Parkinson's disease. In the arteriosclerotic group their results were not nearly so good.

Jolliffe⁵⁷ subsequently reported a group of 32 ambulatory patients with Parkinson's disease. In this latter group he noted that improvement seemed best in the postencephalitic cases. He concludes that the syndrome of paralysis agitans seems to include people who are helped by pyridoxine.

In a group of 12 chronic cases of paralysis agitans (including idiopathic, postencephalitic, and arteriosclerotic) treated with large doses of thiamin, nicotinic acid, riboflavin, and pyridoxine, Loughlin, Myersburg, and Wortis⁵⁸ noted no objective changes for the better. Several of the patients claimed to feel better subjectively, but this was also true for

several control patients who received injections of saline

The reported material is still too meager to draw any definite conclusions, but the evidence at hand suggests that (1) the best results are obtained in cases of short duration, (2) the number of cases helped is small (10 to 20 per cent), and (3) in the latter there is no evidence of any lack of pyridoxine, and the beneficial effects may be related to the general effect of pyridoxine on muscle metabolism

Pseudohypertrophic Muscular Dystrophy—Antopol and Schotland⁵⁹ reported improvement in 6 cases of pseudohypertrophic muscular dystrophy treated with pyridoxine. The treatment was instituted because of the previous finding⁶⁰ that foci of muscle atrophy developed in rats deficient in vitamin B₆. They believed that their results were due to enhanced muscle metabolism and did not imply that this form of muscular dystrophy was due to a lack of vitamin B₆. On the other hand, Ferrebee⁶¹ and his co-workers report entirely negative results in 21 cases of muscular dystrophy (14 of the pseudohypertrophic type), and Wortis⁶² has seen no essential change in 5 cases of pseudohypertrophic muscular dystrophy treated with adequate amounts of vitamin B₆. These contrasts in therapeutic results are difficult to explain and indicate that additional factors may play a part in the results obtained

Spies, Bean, and Ashe⁶³ described a syndrome in 24 people characterized by "extreme nervousness, insomnia, irritability, abdominal pain, weakness, and difficulty in walking," which disappeared dramatically following the intravenous administration of 50 mg of pyridoxine. In some of these cases they were able to confirm their clinical impression of a deficiency of vitamin B₆ by urinary saturation tests. Their clinical reports are rather meager, and the subjective nature of the complaints listed makes therapeutic evaluation even more difficult

Vilter, Aring, and Spies⁶⁴ noted the dramatic improvement of a patient with arsenical peripheral neuritis treated with pyridoxine, but maximal improvement was not obtained until pyridoxine was given together with vitamin E. When thiamin or physiologic saline were substituted for pyridoxine in the early stages of treatment, a relapse occurred

Vitamin E

The experimental work of Evans and Burr,⁶⁵ Goettsch and Pappenheimer,⁶⁶ and Emarson

and Ringsted⁶⁷ has shown that, in the experimental animal, deficiency of vitamin E results in paralysis. Goettsch and Pappenheimer⁶⁶ proved the dystrophic nature of the muscular change in the guinea pig and rat deficient in vitamin E. Emarson and Ringsted⁶⁷ demonstrated that the mature rat fed on a diet deficient in vitamin E developed lesions in the posterior columns and the anterior horns of the spinal cord. They pointed out that in the rat the pyramidal tract is located in the dorsal column and that the disease they were able to produce might, therefore, be compared to the amyotrophic lateral sclerosis syndrome seen in man.

Bicknell,⁶⁸ utilizing these experimental findings, suggested that in the younger individual it was the muscular system while in the older individual it was the nervous system which suffered most in vitamin E deficiency. He reported favorable results in 12 of 13 cases of muscular dystrophy and 2 of 4 cases of amyotrophic lateral sclerosis. His paper, which is in the nature of a preliminary report, is not too well documented, but the author's enthusiasm regarding the results obtained is not to be doubted. This was immediately followed by two exceedingly well-documented reports by Wechsler,^{69,70} who reported favorable results in a series of cases of amyotrophic lateral sclerosis treated with synthetic vitamin E. He pertinently suggests that the syndrome may have varying etiologies and that it is only in the group associated with a deficiency of vitamin E that favorable therapeutic results are to be expected. Of greater significance is his reported observation that on two occasions when the administration of the vitamin E was stopped the weakness returned, and when treatment was resumed recovery promptly resulted. As he points out, this is a crucial physiologic experiment and indicates that the recovery was the direct result of the treatment. Interestingly, the same author observed no particularly significant results in several cases of muscular dystrophy treated with vitamin E. On the other hand, Stone⁷¹ reported excellent results in 5 cases of muscular dystrophy treated with vitamin E and the vitamin B complex. He reports gain in muscle strength, the disappearance of fatigue and muscle pain on slight exertion, change in muscle texture, and replacement of dystrophic musculature by normally contracting muscle tissue. In 2 other cases of muscle atrophy of the spinal and neural type, the results were not quite so spectacular, but "an increase in the amount of regenerated muscle

tissue became apparent after the addition of vitamin E to the vitamin B complex the patient was receiving." Finally, Sheldon,⁷² Ferrebee,⁶¹ Denker,⁷³ Wortis,⁷⁴ and their co-workers have noted no objective improvement in a total of 27 cases of muscular dystrophy, 31 cases of amyotrophic lateral sclerosis, and 4 cases of progressive spinal atrophy treated with large doses of vitamin E, apparently for sufficient periods of time. These discrepancies in reported material from reliable sources require explanation.

Although but three years have elapsed since this subject was last reviewed, the growth of knowledge in this field has been sufficiently steady and solid to warrant this presentation. Some of the material originally presented has been confirmed, some has been discarded, and much remains to be tested. There is a particularly great need for more expert laboratory techniques. We, of course, do not suggest that clinical experimentation should stop until these aids are available, but we do believe that clinical experimentation will be much better directed and therapeutic results much easier to evaluate when these methods become available. We have been impressed with the lack of interest in the psychologic aspects of the various reported illnesses. It must be remembered that individuals attempt to maintain the experience of health even when threatened by a serious illness. The metabolic approach to these "degenerative" diseases has filled both patient and physician with a much-needed optimism, often clouding scientific vision. It would be well to continue our optimism but maintain our scientific critique.

As in vitamin deficiencies occurring elsewhere, those affecting the nervous system are usually the result of multiple, rather than single, deficiencies. Hence, a well-balanced diet should always supplement treatment with the specifically indicated vitamin. Furthermore, the possible synergistic action of vitamins has hardly been touched upon.

It must also be remembered that vitamins are not only accessory foodstuffs but drugs. Thus, nicotinic acid is not only a vitamin but also a vasodilator drug. Its vitamin and enzyme effect need bear no relationship to its use as a vasodilator drug. In the evaluation of the therapeutic efficiency of these substances it must therefore be kept clearly in mind that beneficial results may follow its vitamin (enzyme) effect, its drug effect, or its psychologic effect.

Finally, it must be remembered that ther-

apy, to be most efficacious, must be instituted early. Pathologic conditions are much easier to reverse when treatment is instituted before structural changes have occurred. This fact is worth the utmost consideration in evaluating therapeutic results and may account for many differences in reported observations.

It is our belief that further studies of this type will yield much information of value to students of nervous economy.

Discussion

Dr Noble R. Chambers, *Syracuse, New York*—In these days the practicing physician, whether he is a general practitioner or a specialist, finds himself in a dilemma. Medical literature is full of new methods, new drugs, and particularly vitamins. Every mail brings advertising from the various drug firms. Then the detail man comes in. The radio programs are full of it. The drugstores have vitamin displays in their windows. The world, at least this century, has gone vitamin crazy.

It is, therefore, a real pleasure to hear a paper such as this, taking up each vitamin and its therapeutic uses and presenting in a scientific manner its application to the field of nervous health and disease.

Most of us have not had access to the material nor have we worked so exhaustively in the field as the authors of this paper. Therefore, I shall limit my discussion to a comment and a few questions.

I have not been greatly impressed with the use of thiamin and nicotinic acid in multiple sclerosis.

Though not directly applicable to nervous health and disease, the work of Dr O. D. Chapman, of Syracuse, has shown definitely that not only vitamin C is concerned in oral infections but also the B complex.

I have been impressed with the rather frequent occurrence of a syndrome resembling involution melancholia in both sexes but in individuals far too young for the involutional period, and the prompt relief afforded by adequate vitamin therapy. I have used the B complex in these cases. I have seen 2 or 3 cases of obstinate headache which were pronounced due to either sinus or allergy but were cleared up by vitamin B.

In alcoholism we must never lose sight of the importance of psychotherapy—indeed the effort to revamp the patient's morale must be added to any other therapy if a permanent cure is to be expected.

Questions—(1) What are the recommended dosages of thiamin, riboflavin, nicotinic acid, pyridoxine, and vitamin E? (2) When and why is the parenteral route preferable? (3) When and why is a multiple vitamin preparation preferable? (4) What are the toxic or undesirable effects of vitamins? (5) What about so-called winter depression—is not more than vitamin D concerned?

I have both enjoyed and profited by this excellent paper.

Dr F. C. Southworth, *Buffalo, New York*—This review of the present status of vitamins in neurology and psychiatry is most timely in view of the rapid accumulation of new data and of public confusion based mainly on the claims of advertisers. It appears that we are soon to be able to base our therapy on clear-cut clinical indications.

The idea that neurasthenia may be due to vitamin B deficiency will be welcomed by many psychiatrists who have hesitated to group all such cases with the psychoneuroses. Surely many a doctor has had such symptoms and wondered about his own adjustment.

I believe that most neurologists now accept the principle that polyneuritis in persons suffering from alcoholism is due to vitamin B deficiency and that the same factor is important in some of the brain lesions of alcoholism. That delirium tremens is not primarily due to this deficiency, as Dr Wortis has indicated, is also clear. In 1939 Bowman and Keiser pointed out that the salt metabolism is seriously disturbed in this condition and that administration of sodium chloride cuts short the period of recovery.

The somewhat conflicting reports on the effect of vitamin B₁₂ in paralysis agitans must, I believe, await further evidence before a conclusion can be drawn. Certainly in the symptoms of this disease, mental mechanisms play a most important part. A patient of ours, bedridden for a year with rigidity and tremor, walked on the first day of his treatment with Bulgarian belladonna.

In progressive muscular dystrophy, we have obtained some rather interesting results with vitamin B₁₂ therapy in 13 cases. The patients, pupils in a school for crippled children operated jointly by the Buffalo School Department and the Meyer Memorial Hospital, have been receiving intravenous or intramuscular injections of the synthetic vitamin twice a week for ten months. During this period they have been given quantitative tests for the strength of the principal muscle groups and have also been rated as to general nutrition, intelligence quotient, and social adjustment as indicated by their attitude and performance in classes. Although we have found no definite increase in muscular strength, there has been no decrease during the period of treatment. At the same time there has been marked improvement in general health and performance.

With respect to vitamin E, we have also had some encouraging results in amyotrophic lateral sclerosis. Three patients at the Meyer Memorial Hospital have been under treatment for periods of about a year. Two of these were advanced cases, almost totally disabled when treatment was started. Both have shown complete disappearance of fibrillar twitching, and muscular atrophy and weakness have not increased. In the third case, no gross atrophy was found on admission to the hospital, and the symptoms were of only six months' duration, but there was marked fibrillar twitching, increase in deep reflexes, and bilateral Babinski sign. This patient showed marked and rapid improvement on vitamin E and within a week was completely free from fibrillar twitching. Within two months he was able to work full time at strenuous employment in an industrial plant and has continued to work regularly ever since. His Babinski reactions have disappeared, and his only complaint is cramping of the leg muscles when fatigued.

This case serves to point Dr. Wortis' suggestion—that for good results treatment should be begun early and that the duration of the disease must be considered in the interpretation of therapeutic results.

THE NEW YORK ASSOCIATION FOR THE ADVANCEMENT OF PROFESSIONAL PHARMACY

The annual dinner meeting of the New York Association for the Advancement of Professional Pharmacy was held on Tuesday, June 10, at the Hotel George Washington, New York City.

The following officers were elected: Fred S. Frankfurter, president (brother of Supreme Court Justice Felix Frankfurter), Fred D. Lascoff, first vice-president, Cyrus Hakes, second vice-president, Irving Kantor, third vice-president, Albert Klingmann, treasurer, Fred Roediger, secretary, and Leonard J. Piccoli, executive secretary.

The following were elected to the Advisory Council: Dr. Iago Gladston of The New York Academy of Medicine, Dr. J. Lewis Blass of the First District Dental Society, Calvin Berger, Dean John L. Dandreaux, Anna Grosso, and Harry Read.

A resolution was passed to offer "every possible assistance" of the membership to Mayor Fiorello H. LaGuardia in his National Defense work.

A most interesting program on the Sex Hormones was presented by the following national authorities: Dr. Charles Fay Longfellow, of G. W. Carnrick, presiding, Dr. Erwin Schwenk, of Schering Corporation, "The Chemistry of the Sex Hormones", Dr. James A. Morrell, of E. R. Squibb and Sons, "The Production of the Female Sex Hormones", Dr. Ralph D. Shaner, of Roche-Organon, "Clinical Aspects of the Female Sex Hormones", Dr. William H. Stoner, of Schering Corporation, "Clinical Aspects of the Male Sex Hormones", and Dr. A. MacBrayer, of Ciba Pharmaceutical Products, "Some Non-Sexual Physiologies of Androgenic Substances".

NO APOLOGY NEEDED

A woman who had given a dinner party met her doctor on the street the following day.

"I am so sorry, doctor," she said, "that you were unable to come to my party last night. It would have done you good to be there."

"It has already done me good," he broke in tersely. "I've just prescribed for three of your guests."

—Wall Street Journal

BRAIN STILL USEFUL

William Harvey would never have discovered the circulation of the blood if all he had done was to punchcard the data of Galen. The machine has not been built which can substitute for the human reasoning used in performing a useful physiologic experiment. When it is built, then perhaps a man can allow his brain to atrophy.

—New England J. Med.

FEEDING THE GERMAN ARMY

MAX GERSON, M D , New York City

IN RECENT reports the great efficiency of the German Army has been ascribed not only to its excellent arms and the best of training but also to use of special methods of nutrition. It is important to know what parts of such reports are propaganda and what are the facts. It is the purpose of this paper to describe the nutrition of the German Army and the general directions in which it is further being developed. As a great deal of ground must of necessity be covered, one cannot go into many details or show many of the practical aspects involved.

The science of nutrition had progressed at a rapid pace when the new German government began with the upbuilding of its conscripted army. A host of special problems appeared and were promptly submitted to the leading physicians. Special institutions for their study were established, while schools and courses were set up to distribute the new knowledge. In order to avoid costly mass experiments, physicians acted with extreme caution in the introduction of new methods.

Physical conditions in the new German Army were far less rosy than propaganda would have liked them to appear. Reports in the medicomilitary and medical literature show that even of the most carefully selected men of the Luftwaffe 20 per cent suffered from C hypovitaminosis, army physicians found great difficulties in combating pyorrhea and other dental diseases by means of artificial vitamin C and yeast concentrates.¹ Also, among the powerfully built marines Kruttke² found many cases of vitamin C deficiency with gingivitis and parodontosis. In a more complete summary Rietschel³ explains that scurvy and stomatitis with parodontosis are different diseases, confirming the earlier studies of Salle, Tobler, and others.

In addition, two types of illness are especially in evidence: constipation and the nervous soldier-heart, approximately the same manifestations as in neurocirculatory asthenia.⁴

At the examinations for military services in Kiel in 1934, the number of perfect specimens at 12.6 per cent was frightfully low,⁴ considering that that district is among the healthiest of the country. As a result the requirements for fitness had to be somewhat reduced below the usual standards. Even then

only 55 per cent of those examined in Kiel were accepted for service in 1935.⁶

This human material, physically and nervously even below the average of former years, now had to be strengthened with all available means, increased efficiency was demanded, even new records of performance.

Theory and Practice

The nutrition of the German soldier is based on the requirements of a manual laborer with about 3,500 to 4,000 calories. According to Tyszkas, the American laborer requires 2,800 to 3,000 calories. Poty reports that the American soldier receives 3,500 calories in wartime.

The theoretically calculated average consumption for the recruit is 3,800 calories and that of the man in the field, 4,100. But "not the quantity of the food must be evaluated, but its quality and specific effect."^{5a} There is a clear recognition of the fact that calorie values are useful only for academic calculations. Motorized soldiers require fewer calories than infantry. On the other hand, unless he is well nourished the motorized soldier easily becomes nervous sometimes even to the point of psychosis.⁷ For this reason a good and abundant early breakfast is required, especially when traveling, consisting of strong coffee with much sugar and buttered sandwiches with sausages and eggs. Exhausted troops lacking appetite must undergo cold ablutions in the early morning to stimulate the desire to eat.

The "change to the vegetarian side"^{5b} has become a leading motive, thought to be important not only for increasing efficiency but also for the defense against diseases and their cure. Datner⁹ noticed improvements and cure of neurotic and depressive conditions through a vegetarian diet. The relationship of animal to vegetable food is 18 to 24 per cent animal to 76 to 82 per cent vegetable, though this relationship fluctuates with different types of troops as well as with soldiers from different parts of the country.

The consumption of animal proteins always remains below the calculated maximum figures. "Food richer in protein is necessary in proportion as work performance and the speed of work are increased and more elasticity, activity, and readiness for battle are required."

(so-called "schnellkraftleistung"), on the other hand, "the long distance runner can rather get along with carbohydrates" (so-called "dauerbeanspruchungen") According to German calculations one-third of the total protein intake should be of animal origin, the theoretically calculated fluctuations being between 17 to 40 per cent. In reality, however, this proportion amounts to only 17 to 25 per cent for the various types of troops.

The total protein intake should not fall below 28 Gm. or 0.4 Gm. protein per kilogram of body weight. Experiments with higher protein values showed no improvement over the weight curves of these low-protein values.³⁰

Especially care is taken that milk and its staple products, such as all sorts of hard and soft cheeses including pot cheese, are used in increasing amounts.³¹ On the march, milk powder is preferred, for it keeps for eight months or even ten months if made of skimmed milk. The diet is considerably enriched by means of vegetable proteins, bread and potatoes constituting the main sources. The relationship of protein to carbohydrates is 1:10, that of fat to carbohydrates, 1:3.

According to the science of nutrition the daily requirement of fat is 50 to 70 Gm., with a minimum of 56 to 58 Gm. The daily average requirement for a soldier is calculated at 80 Gm. It is supplied as follows: 35 per cent from butter, 50 per cent from fat contained in meats, cheeses, cream, and sauces, and 15% from margarine and other cooking fats.³²

While the body can build fats synthetically, it has been shown by Stepp and others that it should not be long without the vitamins contained in milk and fats. The best fat is, of course, fresh butter with 0.4 to 20 vitamin D and 2 to 20 mg. carotene.

Carbohydrates with 627 Gm. (about 2,570 calories) daily average are the most important source of energy. The main sources are bread,⁹ potatoes,¹⁰ vegetables, fruits, legumes, and sugar. Bread alone supplies about 40 per cent of the carbohydrate calories.

Bread, therefore, remained an important nutritional problem for the German Army.¹⁰ After much thorough study it was decided to retain the old-fashioned "kommissbrot," made of coarse whole rye, containing all parts of the grain except the outer hull. Hindhede and, more recently, Bickel and Heupke have ascertained that the human digestive tract may be accustomed, like that of animals, to absorb up to 75 per cent of the protein contained in the bran. The recruit gets 750 Gm. of kommiss-

brot daily and, in addition—at least in the beginning—Swedish type of hard tack or graham bread. Kommissbrot contains all of the vitamins B₁ and E found in the grain, and no vitamins are artificially added to it. Scheunert found that flour containing 94 per cent of the grain still had all of the vitamin B₁ of the whole grain.¹⁰ In white bread the vitamins are no longer in evidence, and the addition of bran to the white flour does not give the equivalent of a real whole grain bread.

The daily carbohydrate metabolism consumes a certain amount of vitamin B₁. With hard muscular work and increased metabolism the daily requirement of B₁ exceeds the normal consumption rate of 1 to 2 mg. For increased efficiency the soldier must, therefore, have a greater supply, but even this is easily furnished by a liberal consumption of kommissbrot.

The daily consumption of potatoes for the recruit is 1,000 Gm. and for the older soldier 800 Gm.³¹ This corresponds to 900 and 720 calories, respectively. It is the soldier's most important source of vitamin C, though much of that vitamin is lost during winter storage. In fact, the Germans have now begun breeding a special sort of potato which permits only the smallest possible storage loss of vitamin C. Cooking and steaming, of course, also reduce the vitamin C content. Steaming them in their jackets accounts for the smallest mineral loss, cooking them peeled, the greatest (up to 50 per cent when boiled in salted water). There is a loss of up to 100 per cent when peeled potatoes are exposed to the oxygen of the air.

Fresh vegetables are given in great quantities. Here the main problem is to prevent "killing by cooking" and to make sure of the preservation of all mineral salts.^{11,12} For mass consumption it has been as yet impossible to cook vegetables in their own juices (without the addition of water or steam). Experiments with certain short cooking processes have produced no practical results. It is emphasized that such strongly water-soluble substances as mineral salts and some vitamins (B₁ and C) can hardly be protected during the cooking process and are dissolved in the cooking water. For this reason all of the cooking water of vegetables and potatoes must be used again for soups, sauces, etc., so that their contents of mineral salts will not be lost.¹³ One is well aware of the fact that it is difficult to restore a deficiency of mineral salts in the body cells, though this is certainly possible even though it requires time, since various

poisons must first be eliminated from the cells. In this connection the literature on trans-mineralization seems to have been of great interest.¹² As to canned and salted vegetables, the consensus is that "vegetables salted for the purpose of preserving can hardly any longer be considered carriers of vitamins."¹³

Summary and Conclusion

A. The emphasis is on potatoes prepared in many varieties, kommissbrot, cheese, milk, sour milk, rice, legumes, oat and barley products, flour and pastries, and vegetables and fruits of all sorts, the latter also preserved and cooked with sugar.

B. Meat is quantitatively, as well as with respect to its importance, in a secondary position.¹⁴ Such parts as heart, liver, kidneys, and lungs are much used. Since the army gets foods without restriction, this lessened consumption of meat is not due to a shortage of meat or to any other economic necessity, but it is solely an important result of the newer knowledge of the science of nutrition. In fact, it was a difficult task to get the soldiers used to this new regimen.

C. Aromatic vegetables, such as fresh onions, tomato pulp, and other domestic products, are abundantly used—also liberal quantities of dried vegetables and fruits and many fresh salads, raw and mixed with cooked vegetables.

D. The consumption of spices is kept as low as possible, little salt and pepper are used in order not to replace the original taste of foods by a general and uncertain flavor. Especially recommended is the consumption of yeast extracts, soybeans, and dried vegetables and vegetable powders.

The advantages of dried vegetables and of vegetable powders are so important that they deserve the following brief summary:

1 They are condensed in a relationship of 10:1—that is, 100 pounds of fresh vegetables are reduced to 10 pounds of dried.

2 They are ready to be cooked, absolutely clean, and without any waste.

3 They cook in one-half to two hours. Cabbage, spinach, and green beans are cooked in thirty to thirty-five minutes. Mixtures containing potatoes take longer.

4 All of the vital food elements are preserved. [(?) the author.]

5 They are considerably cheaper than canned foods.

6 Their transportation costs are much lower.

7 There is a considerable saving of time

spent in preparation. For instance, in order to prepare fresh vegetables for 5,000 men, cleaning women have to begin work twenty-four hours in advance. This necessitates keeping the vegetables and potatoes thus cleaned in water until cooking time, with a consequent loss of vitamins and mineral salts.

8 There is a considerable saving in space. 1 cubic meter of dried and pressed vegetables is enough for serving 25,000 to 30,000 portions.¹⁵

9 Ease of transportation (this might be particularly valuable if America were to assume the burden of feeding certain parts of Europe).

10 No bacterial contaminations—especially important where troops have no access to fresh, clean foods.

11 Dried vegetables and vegetable powders taste good.

The German military authorities seem to realize that much improvement is still possible and to this end certain general principles have been laid down.¹⁶

a The consumption of meat and meat products must not be increased.¹⁷

b The consumption of fish should be increased,¹⁸ partly for reasons of national economy. At present the consumption of fish is about one-fifth of that of meat.¹⁹

c There should be a more abundant consumption of milk and milk products.

d The consumption of bread and potatoes should be increased.

e Likewise, there should be increased consumption of vegetables and fruits.

It follows that the German army "intends to fully exploit to the utmost such sources of food as are not yet fully used, and to change the nutrition as a whole still more to the vegetarian side."²⁰ In order to improve the preparation of foods so as to make them more to the liking of the soldiers, the waste contained in garbage cans is carefully scrutinized every day. The garbage can has thus become a valuable guide and great teacher in perfecting the daily menu.

The question of vitamins assumes a position of pre-eminent importance in relation to the problem of increasing efficiency. Since increased efficiency is predicated on increased metabolism and oxidation, the consequent consumption of increased quantities of vitamins must be insured.²¹ Rietschel's suggestion of preferring natural vitamins is accepted as far as possible. In enriching the diet with natural vitamins the relationship in which these vitamins occur in nature must be

chosen, for vitamin tables and the results of studies of vitamin metabolism are still too uncertain¹⁶ The addition of artificial vitamins to fresh or preserved foodstuffs is rejected Rejected likewise is that the field kitchen be supplied with an assortment of vitamin concentrates The Swiss army has experimented with an artificial vitamin preparation (Guigoz 3 consisting of vitamins C and B, mineral salts and iron, dried yeast 10 per cent, and glutathione) The results have been poor^{15b} Dalldorf's statement, "A dollar will buy more vitamins in the market than in the drugstore,"^{15a} may be considered the *Leitmotive* in solving the vitamin problem for the German army

As everywhere in the living body, so in its relationship to vitamins harmony must exist, vitamins must be in their proper relationship to each other as well as to the hormones¹⁷ and mineral salts¹⁶ If this factor is overlooked, the water-soluble vitamins C and B may act against the fat-soluble A and E For instance, to restore balance, A hypervitaminosis may be compensated by an increase of the B and C reserves Finally, even A and B may act against each other The interpretation of clinical reports becomes increasingly difficult because lack of vitamin D in the diet may create similar phenomena as an excess of A In 1936 an American radio lecturer induced mothers to give their children more codliver oil But with vitamin D these children also received too great a dose of vitamin A, and thus experimental scurvy was produced despite the fact that these children had an abundant supply of orange juice The lesson was that excessive doses of vitamin A suppress the function of vitamin C

In German experiments with artificial vitamin C tablets (Redozon tablets) increased sport performances could be obtained by girl students without damage, but only temporarily Ragnar Berg was the first to emphasize that the effectiveness of vitamins depends on a surplus of alkali foods¹³ I found in my own studies that the replenishment of the mineral metabolism with the potassium group is a prerequisite for the vitamin replenishment and consequent increased efficiency of the cells¹² This has become a basic principle of nutrition which is now being practically carried out by way of increased consumption of vegetables and fruits, of whole grain bread, and in the utilization of the cooking waters of vegetables, potatoes, etc

The German authorities have only reluctantly developed special diets intended to ac-

complish special physical and technical performances The following brief summary emphasizes only certain characteristic features

1 Recruits receive, in general, an excess quantity of foods, even so, 70 per cent of them lose weight during the first half year because of the unaccustomed physical requirements

2 Members of the air corps get preference in everything

3 The troops in the field receive the largest quantities of everything, but infantry on the march gets almost as much

4 A special preparation of fruit and grape sugar, powdered meat, fat, milk protein, vitamins of vegetable origin, and fruit essence is given to overcome dryness of the throat and thirst

5 Most troops carry with them a lemon powder to improve the drinking water—5 Gm being sufficient for 1 pint of water

6 Motorized troops receive more refreshments, such as lemonade, and smaller quantities of food at more frequent intervals They also get more frequent rest periods¹¹

7 Soldiers in forts and below the surface get food especially rich in vitamin D, such as smoked fish, sea fish, butter, eggs, fat cheeses, milk, yeast extracts, etc

8 Soldiers in subterranean and fortified positions receive foods that are especially durable and take little space, such as vegetable and potato powder, milk powder, and vitamin D supplements as under No 7

9 Parachutists get liver sausages, Swedish-type hardtack, and vitamin C tablets

10 Troops serving in the tropics, especially, get many fruit preserves frozen at low temperatures¹³ and milk powder

11 Troops serving in the arctic receive (following Friedjoff Nansen) a mixture of meat and vegetable powders, milk powders, and dried pressed fruits

The problem of increasing the performance of the soldiers is, however, a complex one, necessitating the solution of numerous special problems Included among these are the physiologic principles of fatigue and recuperation Meyerhoff-Hill's point of view that the lactic acid contents of the muscles correspond to the degree of fatigue and that general fatigue is due to increasing acid content in the blood has been generally retained However, during the last ten years certain fundamental studies have been reported by the Prague and Viennese schools which proved that during exertion the muscle cells lose potassium, and sodium takes its place Thus, the potassium contents of the muscle of well-rested rats

TABLE 1*

	Number of Animals	K mg %	Na	Ca	Cl	K/Na	Number of Animals	K, mg %	Na	Ca	Cl	K/Na	Duration of Running
Muscles	29	439	109	11	40	2 38	31	414	117	12	35	2 09	18 hr
Heart	29	411	125	11		1 94	31	394	142	10		1 64	18 hr
Liver	29	428	99	8	69	2 55	31	350	117	9	60	1 76	18 hr

* From Eppinger Arch. f exper Path u Th. Bd 133 509-524

averages 439 mg per hundred cubic centimeters, but only 414 mg per hundred cubic centimeters after twenty-four hours of running. Fatigue increases the sodium content from 109 to 117 mg per hundred cubic centimeters. The potassium loss due to fatigue is not limited to the muscles of skeleton and heart but affects the other organs as well, as shown in Table 1.

In other words, for the problems of fatigue and recuperation the mineral metabolism rather than the simple food metabolism with glycogen plays the decisive role. In fatigue, therefore, a light transmineralization occurs because of changes in the "directed permeability" of the cell membranes and walls of the capillaries. The result is PO₄ and Ca leave the cell and enter the blood, lymph, and the connective tissues, while Na, H₂O, and Cl go from the blood into the cells of muscles, nerves, liver, etc.

Roller¹⁹ describes the fatigued cell as follows "edema of the cell, cloudy swelling, increasing distance of the cell from the capillary, and protein excretion into the interstices." The entire regulatory mechanism of the cell suffers, the wall separating it from its liquid surroundings becomes permeable, and gradually the tension between the cell contents and its surroundings declines. It is as yet undecided in what stage the greater potassium loss of the cell occurs, but it is certain that there exists at once a relative impoverishment of potassium. There follow changes in the limiting surfaces between nucleus and protoplasm. If this pathologic event is accelerated, serous inflammations begin. The cell membrane is assisted in its function by an intermediary substance located between the cell and the nourishing capillary. This substance aids the parenchyma cell in permitting the exit of used-up substances and in keeping harmful substances out. The normal cell membrane retains a high-potassium content within the cell and prevents sodium and other substances from entering.

Needless to say that sodium and its derivatives are no longer given for fatigue and in inflammations, for the temporary relief is followed by increased weakening.

Another important problem was how soldiers could be helped to eliminate fatigue-creating substances. Investigations with the capillary microscope have shown that the capillary system performs a great part of this task and that only after restoring the function of the capillaries can fatigue-induced edema of the cell be overcome or inflammation be cured. The daily intake of all protoplasmic poisons has, therefore, been reduced to a minimum, including the consumption of nicotine, alcohol, tea, and hot spices, as well as excessive metabolic stimulation from protein overfeeding. It is well known that sport performances cannot be combined with the consumption of alcohol, much less record performances that burden all body organs to the utmost.

In conclusion, it may be briefly emphasized that the preference for a vegetarian nutrition by the German army is based on the extensive fatigue studies by Keller,²⁰ Eppinger,²¹ Kaunitz,²² Roller, and others. Keller has developed the classification of mineral salts into potassium and sodium groups within the animal and vegetable kingdom and found their electrical transformation in "biologic milieu." Of course, they are not the only powerful biologic forces, but their great significance for practical usefulness has been demonstrated, among others, by the increased efficiency of the soldiers nourished with the help of this knowledge.

One moral remains to be added: it is a terrible tragedy and paradox that the accomplishments of the new technique in the science of nutrition should now be used without limitation for the demolition of human life. Far better fields could be found for putting this progress to work than causing death and destruction.

LABORATORY AIDS IN THE DIAGNOSIS OF GONOCOCCIC INFECTION

In the past the laboratory has aided in the diagnosis of gonococccic infection solely by the examination of stained films prepared from exudates. With the development of improved cultural methods, a new and more reliable diagnostic procedure has become available. Film examinations are dependable aids only in the diagnosis of acute infections in men. The cultural method should be used in the case of women, of patients with chronic infection, or as a test for cure, particularly after treatment with sulfonamide compounds. Film and cultural examinations together give the best results.

Sources of Material.—Material for films and cultures may be collected from the same source. In acute infections in the male, pus is obtained from the urethra. In chronic infections, urethral exudate is examined if present. Urine and prostatic secretion may also be cultured. In the female, pus is collected from the urethra and cervix. In vulvovaginitis, exudate is obtained from the vagina, preferably with a glass catheter. Additional sources of pus are Bartholin's glands, the fallopian tubes and other infected pelvic tissues removed at operation. In both sexes extragenital infections, such as conjunctivitis, proctitis, endocarditis, arthritis, and atypical meningitis, may occur. Appropriate material—exudate, urine, blood, joint fluid, cerebrospinal fluid, etc.—may be submitted for cultural examination. (Statistics indicate that 2 per cent of all cases of meningitis are due to the gonococcus.)

Collection of Specimens.—Pus is collected on a dry, sterile swab which is rotated over the surface of a slide to give a thin film. Material for cultural examination is collected on another swab which is put immediately into a tube containing approximately 1 ml of nutrient broth.

Prostatic secretion is obtained by massaging the prostate while the patient constricts the urethra with the thumb and forefinger. It is collected in a tube containing 1 ml. of broth. First-voided urine, from 5 to 10 ml in a sterile tube, constitutes a satisfactory specimen. A sterile swab is employed for obtaining specimens from the female urethra after it has been stripped. For cervical or vaginal specimens, a speculum should always be used, preferably without a lubricant. To obtain rectal discharge the anal orifice is cleansed and the swab inserted into the anal canal.

Specimens for cultural examination must be received by the laboratory as soon as possible, never more than six hours after collection. Hence, they should be delivered by messenger. Until cultured they should be kept at icebox or room temperature, not in an incubator. Cultural examination should be undertaken only in a properly equipped laboratory with trained personnel.

Interpretation of Laboratory Findings.—Failure to demonstrate gonococci by culture or to find typical intracellular gram-negative diplococci in films made after treatment or taken from patients with chronic infection, is insufficient evidence of cure. The presence of extracellular microorganisms, while inconclusive, is suggestive of the disease. In all such cases material for both morphologic and cultural examination should be sent again to the laboratory.

The complement fixation test in its present stage of development is not a reliable diagnostic procedure. In certain cases, however, it may be helpful when appraised in the light of clinical and other laboratory findings.—Issued by the New York State Association of Public Health Laboratories, Leaflet No 17.

ORIGIN OF GREAT CLINICIANS

There is no better student than the son of a medical father if the boy's heart is in the work, but none is worse than he who, not caring for, or even disliking, the practice of medicine, is urged on by a medical parent to qualify in order to take his place. Better even than the student who, having family traditions, takes to medicine almost by instinct is the boy who, lacking any such associations, determines, whilst still a child, that he will be a doctor. For, in this last case, he may have more than an ideal to study and to id-

vance the science of medicine—he may have a real call to heal the sick and alleviate human suffering. It is from this class that the truly great clinician is derived. Often these students are what might be termed freaks in their families. They appear in every social stratum, and their early decision to become doctors seems often to be unrelated to any outside circumstances.—*F Wood Jones, in Doctors in Shirt Sleeves* edited by Sir Henry Bashford, London, Kegan Paul, Trench, Trubner & Co, Ltd, 1939.

Diagnosis

CLINICOPATHOLOGICAL CONFERENCES

DEPARTMENTS OF MEDICINE AND PATHOLOGY, NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL, COLUMBIA UNIVERSITY

Date March 18, 1941

Presiding Dr Irving S Wright

History

DR ROBERT McGRATH This patient was a 45-year-old white man who was followed in the dispensary and hospital over a period of seven years. He had been rejected for military service in 1918 because of a heart murmur. No history of acute rheumatic fever or its cardiac equivalents could be elicited.

He was first seen in the dispensary in November, 1934. For three months prior to this he had complained of dyspnea on exertion, palpitation, and fatigue.

Examination at that time revealed the following significant findings: (1) moderate obesity, (2) blood pressure, 190/110 mm of mercury, (3) left ventricular enlargement, (4) a systolic thrill in the second right interspace, (5) a faint systolic murmur at the apex, (6) a rough systolic murmur at the aortic area which was transmitted upward and was also heard over the chest posteriorly, (7) a faint diastolic murmur at the aortic area transmitted along the left sternal border, (8) absent arterial pulsations in the legs, and (9) unsatisfactory blood pressure determinations in the legs. Urinalysis at that time was normal in all respects. The blood Wassermann reaction was negative for syphilis. The electrocardiogram (Fig 1A) showed a left axis deviation, depressed ST_1 , elevated ST_2 , biphasic T_1 , high voltage QRS. The QRS conduction time was 0.11 second. An x-ray of the chest revealed cardiac enlargement with predominance of the left ventricle, the aortic arch was knuckled and prominent.

The patient was put on an anti-obesity regimen and was advised to restrict his activities to avoid dyspnea. He improved under this treatment.

Between 1934 and 1936 his condition remained essentially unchanged. The blood pressure averaged 170/100 mm of mercury. His occupation as a water inspector required considerable walking, which he was able to carry out despite slight shortness of breath. An electrocardiogram (Fig 1B) taken in 1935

showed changes from the tracing of 1934 consisting of further depression of ST_1 and changes in the form of T_2 and T_3 .

In 1937 he developed episodes of severe pain in the lumbar region which radiated down both legs. This pain was initiated by effort and would disappear with rest. There were no definite changes in the murmurs. An electrocardiogram (Fig 1C) at this time showed alterations in the direction of normal. A chest x-ray in December, 1937, showed marked left ventricular enlargement with a prominent aortic knob. It was further noted that the descending aorta immediately below the knob appeared retracted. Some notching of the inferior margins of the ribs was reported.

During 1938 the patient was better symptomatically and did not complain of the pain in the back and legs. The blood pressure was 160/90 mm of mercury.

In 1939 he was working as usual but his dyspnea was more pronounced. Precordial pain was produced by effort and relieved by nitroglycerin. The pain in the legs did not recur. During this period the patient experienced two attacks of extreme dyspnea lasting several hours. The blood pressure had dropped to 138/100 mm of mercury.

He was hospitalized for a week in December, 1939, for mild congestive failure. The following blood pressure readings were recorded: arms, right 138/110 and left 142/112, thighs, right 124/110 and left 120/106.

Urinalysis showed a specific gravity of 1.030 and was negative for albumin, red blood cells, and casts. The blood count was normal.

In January, 1940, the patient found it necessary to change to a more sedentary occupation because of the increasing severity of his symptoms. He was digitalized and given mercurin suppositories but congestive failure gradually increased. An electrocardiogram (Fig 1D) taken in March, 1940, showed a rate of 105 per minute with left axis deviation. Depression of ST_1 and elevation of ST_2 were present. The patient was taking digitalis at this time and the changes noted were believed to represent left ventricular strain with digitalis effect.

FIG 1

In October, 1940, the patient was acutely ill and in advanced congestive failure. The blood pressure had fallen to 92/76 mm of mercury. Immediate hospitalization was advised but the patient refused. Three days later he was admitted as an emergency case and died within an hour.

DR IRVING S. WRIGHT: Dr. Flexner will discuss this case from the point of view of differential diagnosis without the benefit of the pathologic findings, which will be presented at the end of the general discussion.

Discussion

DR JAMES FLEXNER: In considering this case we can take any one of the essential findings and develop the differential diagnosis. I should like to start with a discussion of the hypertension. In a general classification of diastolic hypertension, we can implicate four main systems: the nervous, the renal, the endocrine, and the vascular systems. On all occasions the urinalyses were normal. We may rule out, therefore, the renal system as a cause of the hypertension. There is nothing in the history or physical findings to involve the nervous system. In the endocrine system we must consider the possibility of a tumor of the adrenal gland or pituitary basophilism, but there is no evidence to substantiate this contention. Under the vascular

system we can consider the following causes of hypertension: (1) periarteritis nodosa, (2) lead poisoning, (3) thromboangitis obliterans involving the renal artery, and (4) coarctation of the aorta.

The absence of peripheral neuritis, eosinophilia, nephritis, fever, vague shifting symptoms, and periarterial nodules makes the diagnosis of periarteritis nodosa unlikely. There was no history of exposure to lead. No lead line of the gums, stippling of the red cells, abdominal cramps, or wrist drop was present. This, I believe, rules out the diagnosis of lead poisoning. If the hypertension was due to thromboangitis obliterans, more renal involvement would be expected. In addition, at least one of the extremities probably would have been involved.

The diagnosis of coarctation of the aorta will explain many of the findings in this case. The patient's murmurs were discovered at the age of 23. Murmurs discovered at this age or earlier are usually due to a congenital heart lesion or to rheumatic valvulitis. We have no history of rheumatic fever and so I should like to discuss the diagnosis of coarctation of the aorta.

There are two types of coarctation. One is the infantile type present at birth, frequently completely obstructing the aorta and, therefore, being incompatible with life. In the adult type there is a slowly progressive constriction at or near the insertion of the ductus arteriosus. A theory proposed for the explanation of the adult type of coarctation supposes that a portion of the retractile tissue of the ductus arteriosus extends into the aorta and, as atresia occurs in the ductus after birth, a stringlike constriction is exerted about the aorta. Absence or prominence of the aortic knob depends upon the site of this constriction. Since the narrowing takes place slowly, collateral circulation develops. If this collateral circulation develops below the arch of the aorta, anastomoses between the internal mammary artery and thoracic aorta via the intercostal arteries become prominent. There are also prominent anastomoses about the scapulas. These collateral vessels can often be seen and palpated. At times these large pulsating collaterals cause bony erosions such as occurred along the inferior rib margins in this case.

The hypertension of coarctation of the aorta may be explained by the mechanism of renal ischemia. In animal experiments Steele¹

¹ Steele J. M. Proc. Soc. Exper. Biol. & Med. 41: 86 (1939).

noted an elevation of the diastolic pressures in the upper and lower extremities when the aorta was partially clamped above the origin of the renal arteries. A systolic rise also occurred in the upper extremities but was absent in the lower extremities because of dissipation of the pressure in collateral vessels.

There are certain discrepancies in the blood pressure in this case. These consist of intermittent drops in the systolic pressures. If these changes are not due to the different standards of various observers, they may be explained by an improvement in the collateral circulation. This also could account for the disappearance of his intermittent claudication. The systolic murmur was probably due to the narrowing of the aorta and could be heard over the entire chest along the course of the dilated blood vessels. The other murmurs present may have been due to secondary valvular changes or myocardial dilatation. Frequently, there are associated congenital defects. The commonest of these are bicuspid aortic valves, patent foramen ovale, and patent interventricular septum. Abbott,² in reviewing 140 cases, found that the causes of death were as follows: congestive heart failure, 60, rupture of the aorta, 38, cerebral complications, 26, bacterial endocarditis, 14, and sudden heart rupture, 2.

Dr. Flexner's Diagnoses

Coarctation of the aorta, adult type

Congestive heart failure

DR. WRIGHT: Does anyone wish to suggest other diagnoses?

DR. MACK LIPKIN: From the description of the electrocardiogram and clinical history we may add to the diagnosis of coarctation of the aorta, coronary sclerosis with myocardial damage.

DR. WRIGHT: It seems to me that unexplained or essential hypertension should be considered in this list, at least from the point of view of differential diagnosis.

DR. J. SCOTT BUTTERWORTH: On his first admission the blood pressure was 190/110 and there was a continual fall until on the final admission it was 138/100. At the same time the blood pressure in the legs increased and was not far from normal. What would be the explanation of the decreasing tension in the upper extremities and the increasing tension in the lower extremities?

DR. FLENER: The 20 points difference in the systolic readings in the arms was probably emotional. When his systolic pressure de-

creased to 138 mm of mercury it was evidence of myocardial weakness. From Steele's¹ work a rise in diastolic pressure in either extremity would suggest further renal ischemia, while a rise in systolic pressure in the legs would indicate an improvement in collateral circulation.

DR. WRIGHT: In the cases of coarctation of the aorta which I have reviewed there were few that showed a pressure in the lower extremities as high as that obtained in this case. Taking the blood pressure in the legs is often difficult and may be subject to error.

Pathology

DR. MAURICE N. RICHTER: The principal changes of interest were all in the aorta and in the heart. I wish to point out the narrowing of the aorta which is below the attachment of the ductus arteriosus. There also is a marked stenosis of the aortic valve which has only two cusps. There was comparatively little arterial anastomosis demonstrated at the time of autopsy. The intercostal vessels were not very much dilated, but notching of the ribs was evident. There was also a moderate amount of stenosis of the coronary arteries and considerable thickening of the intima. There was fibrosis of the apex of the left ventricle and fluid in both pleural cavities.

In view of the fact that we have both a stenosis of the aorta and a stenosis of the aortic valve, I think we may have an explanation for the small amount of collateral circulation and the progressive decrease in the systolic pressure. The small aortic valve probably reduced the amount of blood in the ascending aorta, and the supply for collateral circulation was minimal. In coarctation of the aorta a bicuspid aortic valve, probably of congenital origin, is present in 20 per cent of the cases. We have not studied this particular aortic valve by the method of Lewis and Grant³ to determine whether it is congenital in origin because we wished to preserve the specimen. It might be interesting to do so, however, because few bicuspid valves have been studied in this fashion.

Pathologic Diagnoses

Coarctation of the aorta. Stenosis of the aortic valve.

Stenosis of the coronary arteries. Fibrosis of the myocardium.

Hyperplasia of the heart.

¹ Abbott, M. E. *Am. Heart J.* 3: 579 (1923).

² Lewis, T. and Grant, R. T. *Heart* 10: 21 (1923).

Chronic passive congestion of the viscera and ascites

DR JAN NYBOER In evaluating the electrocardiograms, the findings in 1934 and 1935 of high voltage, left axis deviation, and changes in the S-T segments and T waves are consistent with left ventricular enlargement due to hypertrophy of any etiology. The reduction in voltage in 1937 and further reduction in 1940 without other significant change is not easily explained. The drop in blood pressure due to concomitant aortic stenosis is probably not the cause. Impending or definite cardiac failure may be responsible for the changes in 1940.

DR WRIGHT I wish to point out that there has been progress in clinical medicine as well as laboratory medicine. An article by Sir Thomas Lewis¹ describes a situation

¹ Lewis T. Heart 16 210 (1933)

that existed in England during the last war. A young man was hospitalized for six months with unexplained hypertension. During his stay he was "examined more than once by Sir William Osler and Sir James Mackenzie, both of whom were much interested in his state. But the coarctation of his aorta remained undiagnosed." Today we feel that an intern should make the diagnosis of coarctation of the aorta promptly and without difficulty on the basis of a thorough physical examination including blood pressure studies of all extremities.

MAURICE R CHASSIN, M D

HERMAN O MOSENTHAL, M D, *Chairman*

WAR AND INFECTIOUS DISEASE

The waging of war has always been attended by increases in the prevalence of disease, notes Clara E. Council, junior statistician of the United States Public Health Service in *Public Health Reports* (Washington). The rapid and extensive spread of infection is to be expected under the conditions brought about by the struggles between nations. The concentration and movement of large bodies of men from various parts of the world, the limitless hardships, with fatigue, general malnutrition, famine and exposure, and the lack of medical care, sanitation, and personal hygiene often experienced by civilians and soldiers alike provide the fuses for the explosion of widespread epidemics. Refugees and captured and returning prisoners are important instruments in the transmission of disease from enemy to enemy and to all civilian groups. While certain types of sickness have accompanied armies throughout the centuries, there have nevertheless been some notable changes in the prevalence and severity of wartime affections. It is only in comparatively recent wars that more men have been lost from military action than from disease. The ratio of the disease death rate to the battle death rate among United States troops was 7 to 1 in the Mexican War and 5 to 1 in the Spanish War. The Germans in the Franco-Prussian War of 1870 and the Japanese and Russians in the Russo-Japanese War of 1904 show the first records in which the mortality for the wounded was higher than for those stricken with infectious disease.

During and after the first World War, the common war diseases were highly prevalent in Eastern Europe, and there was a vicious pestilence of typhus fever throughout Russia, Poland, and Serbia. Typhus did not spread in western Europe in these war years, and the classic infections did not constitute the major sickness problems among fighting forces or civilians. The influenza pandemic overshadowed all

others, and the mortality from influenza and pneumonia recalled the ravages of the Black Death. Cerebrospinal meningitis reached new heights, and tuberculosis and venereal disease increases caused grave concern.

In the United States Army, influenza, venereal diseases, mumps, and measles were the most frequent causes of absence from duty, and influenza, tuberculosis, measles, and cerebrospinal meningitis were leading primary causes of death. The Army in the United States had generally higher rates for admission and days lost from duty for the infectious diseases than did forces abroad. The United States Navy also suffered from the communicable diseases, with a notably higher incidence in the training camps than on shipboard.

In the present war, influenza and cerebrospinal meningitis are again showing increased incidence, both for the Continent and the British Isles. Typhus fever and dysentery have been active in eastern Europe.

The evacuation of school children did not result in the expected increase in the communicable diseases of childhood in England, and for the most part the health of the people has not been seriously affected. The hazards of infection have, however, been intensified by the crowding of the bomb shelters. Not only influenza and cerebrospinal meningitis but also paratyphoid fever and dysentery showed increases in 1940 in comparison with 1939.

In the control of disease as in the fighting of battles the experience of the past can provide no rigid rules for present victory. Nevertheless, an appreciation of former problems may facilitate their solution in later experience. The changed character of the leading infectious diseases of war, with relegation to the background of the scourges of the past, may be considered a heartening reflection of the results of scientific research and control.

Morphogenesis and Significance of So-Called Intercapillary Glomerulosclerosis— A Lesion of Diabetes Mellitus * Dr Arthur C Allen (*by invitation*)

Some four years ago Kimmelstiel and Wilson reported a series of cases in which they demonstrated the association of a characteristic clinical syndrome with a peculiar type of glomerular hyalinization which they called "intercapillary glomerulosclerosis." The clinical complex consisted typically of diabetes, hypertension, and the nephrotic syndrome. This association was subsequently confirmed by several observers. However, a number of key questions remain unanswered, such as (1) Does the lesion occur only in diabetic patients? (2) Is there a correlation between the severity of the clinical picture and the extent of the lesions? (3) What is the morphogenesis of the lesion and its role in the abnormal clinical physiology?

We studied the kidneys of 105 consecutive diabetic patients over the age of 40, 100 non-diabetic hypertensive patients over the age of 40 with a blood pressure of 160/90 or greater, 100 consecutive nondiabetic, nonhypertensive controls of all ages, and 34 unselected subacute and chronic glomerulonephritis patients. The glomerular lesion of Kimmelstiel and Wilson was found in 33 per cent of the persons suffering from diabetes, in only 1 of the hypertensive groups, and in none of the others. Two additional cases with the lesion were found in which the diagnosis of diabetes could not be made nor excluded because of the inadequate clinical workup due to their expiration shortly after admission. It is felt that this glomerular lesion may be unequivocally differentiated from the glomerular atrophy of ordinary nephrosclerosis by the following features: (1) the characteristic oval or disk-shaped hyaline mass surrounded by one or more concentric layers of displaced endothelial and epithelial cells and circumscribed by a rim of thin-walled capillaries, (2) its response to silver stains, manifesting either a characteristically laminated argyrophilia or

the mahogany brown of dense collagen which sharply differentiates it from the remainder of the uninvolved portions of the glomerulus, and (3) its relative resistance to tryptic digestion.

A study of serial sections revealed that the lesion appears to be derived from a thickening and fusion of the capillary walls rather than from the intercapillary tissue. Therefore, it is suggested that the lesion described by Kimmelstiel and Wilson be regarded as intramural or *focal capillary glomerulosclerosis* rather than as *intercapillary glomerulosclerosis*.

Afferent arteriosclerosis is a practically constant concomitant of the lesion. However, in addition, appreciable *efferent* arteriosclerosis is found in severe cases. This is stressed, first, because of its reported absence (*Am J Path* 6: 347, 1930) in the ordinary nephrosclerotic kidneys of hypertensive patients, second, because of the increasingly important role in glomerular dynamics to which this arteriole is being assigned, and, third, because the pressor substance in experimental hypertension is presumed to act on the efferent arteriole, which in these diabetic hypertensive patients is narrowed organically.

The presence of dilated, congested capillary loops showing evidence of stasis and their constant association with the diabetic glomerular lesion suggests that they may thereby be a factor in the albuminuria. Occasionally, some of these loops are extraordinarily dilated and contain small fibrin clots, protein precipitate, and laked blood.

Because of the admittedly unsatisfactory nature of the histologic criteria currently used for the diagnosis of diabetes and because of the clear-cut nature and high incidence of the lesion in these diabetic patients, it is suggested that this lesion be used as a

* To be published in full in *Arch Path*

morphologic criterion for the diagnosis of diabetes in persons over the age of 40

As a result of a collaborated study with Dr Sheppard Siegal (*Am J M Sc*, in print), we found that a more or less positive correlation existed between the severity of the syndrome and the extent of the lesions. It should be pointed out that the diabetes in most of these cases is characteristically mild, some requiring little or no insulin at all for the control of the diabetes. It may be mentioned, further, that no specific lesion was found in the pancreas in these cases.

Discussion

DR HANS SMETANA. Dr Horn and I were interested in this condition, and we went over our material of 150 cases of diabetes. We were struck by the constant relationship between arteriolar changes and glomerulosclerosis and examined the material from this point of view. We could not find any case of glomerulosclerosis without renal arteriolar sclerosis. We also compared this material with about an equal number of cases of noncomplicated renal arteriosclerosis. We found similar globules in about the same percentage in noncomplicated, renal arteriosclerosis as in the cases complicated by diabetes, but the bodies were more numerous or more glomeruli were affected in the cases of arteriosclerosis complicated by diabetes than in the noncomplicated arteriosclerosis cases. We also could not find any constant relationship between the number of bodies and the amount of albuminuria, the age, grade of hypertension, or any other factors. We thought there might be some relationship between the glomerulosclerosis and treatment of diabetes with insulin and, therefore, we went over our cases that had occurred

before the institution of insulin therapy. We found few cases of glomerulosclerosis in this era but, since patients with diabetes usually did not live long before the treatment with insulin, we discarded this finding.

DR PAUL KLEMPERER. I have examined some 305 consecutive cases without knowing anything about the clinical histories, and I could find 28 cases in which I could recognize this lesion without difficulty, there were only 2 cases in which I was somewhat in doubt. I feel these lesions are easily and definitely differentiable from those of ordinary nephrosclerosis. Of these 28 positive cases, 27 had diabetes.

DR ARTHUR C ALLEN. I am unable to account for Dr Smetana's observation of this glomerular lesion with such remarkable frequency in the nondiabetic cases. Naturally, I should enjoy examining such a group of nondiabetic hypertensive patients for that purpose. I studied the relationship to the clinical syndrome in collaboration with Dr Sheppard Siegal, who unfortunately cannot be here tonight. He divided the cases clinically into three groups, without letting me know about the actual division. One group consisted of the diabetic persons without hypertension or any of the renal component, the second group consisted of persons with diabetes and hypertension and little of the renal element clinically, and the third group was the more or less full-blown syndrome. The actual data are to be published shortly in the *American Journal of the Medical Sciences*. Briefly, we found, in general, a fairly reasonable correlation between the severity of the clinical syndrome and the distribution of the lesion, which we graded as 1 plus, 2 plus, 3 plus, and 4 plus.

Morphologic Analysis of Tuberculous Lesions in Adults. Dr Kornel Terplan, Buffalo, New York (by invitation)

Any attempt at the pathogenetic analysis of tuberculous lesions must be based on a thorough knowledge of the different types of the primary infection, including especially the primary complex. At postmortem examination of adults who died from different causes and of those with progressive fatal tuberculosis, it must be determined whether or not a direct or indirect connection between the lesions of the primary complex and all so-called postprimary lesions can be established. With the increasing material examined, each case looks more and more like an individual

problem. A few local lesions as incidental postmortem findings with more limited spread are especially favorable for successful pathogenetic studies. These are more complicated in cases of chronic pulmonary and visceral tuberculosis with extensive changes. No correlation of the variety of lesions to immunologic theories is attempted in this study. The incidence of tuberculous lesions in children below 6 years of age is between 5 and 6 per cent, from the seventh to the eighteenth year, between 20 and 25 per cent. In adults from the eighteenth to the fortieth year the

percentage of positives varies from 70 to 90 per cent. Beyond the age of 45 entirely negative cases are exceptional. The tabulation of tuberculous lesions found in about 270 adults between 19 and 80 years of age in relation to their probable pathogenesis is presented, including cases of tuberculosis as the major causes of death and many cases in which tuberculous lesions were incidental.

Among 267 adults between 19 and 80 years of age, recent primary tuberculosis was found in 33, 2 typical tuberculous complexes (Ranke) of different ages (1 healed, the other recent), in 22, and a recent caseated complex in the presence of a healed primary focus without corresponding lesions in the lymph nodes was found in 7 cases. In addition, a primary focus without gross or microscopic evidence of tuberculosis in the regional lymph nodes was present in 20 cases. Recent focal tuberculous lesions, as incidental findings (mostly in one subapical area) in the presence of a healed stony complex, were found in 17 cases. In none of these were hematogenous lesions observed. In 13 cases with a recent caseated complex as an incidental finding, one or more additional caseated foci in subapical fields or in lower lobes were seen which had the same histologic structure as the primary focus. There was no evidence of hematogenous seeding in these cases. Chronic pulmonary tuberculosis with intrabronchial spread of the well-known picture of the so-called reinfection type was present in 18 cases. In all of these, remnants of an old first infection—namely, an ossified or stony complex—were demonstrated. In 8 cases the lymph node groups regional to the progressive post-primary pulmonary lesions showed marked tuberculous lesions similar to those seen in lymph nodes adjoining an active Ghon focus of first infection. The anatomic picture in the majority of the cases of this group pointed to exogenous reinfection or superinfection of the lungs. In 2 instances a healed stony complex of primary intestinal tuberculosis was found with an overwhelming recent tuberculous bronchopneumonia with extensive intrabronchial spread. This was obviously an effect of true exogenous reinfection.

Of the 33 cases with a relatively recent complex, in 15, progressive tuberculosis with hematogenous or intrabronchial spread had developed. In only 3 cases out of 28, progressive hematogenous or intrabronchial tuberculosis was caused by the recent complex of a secondary infection.

Many incidental findings in such cases

where death was not caused by tuberculosis are of considerable significance for a better understanding of the pathogenesis of tuberculous lesions. This applies especially to the apical and subapical foci. Our material contains many cases in which these mostly single focal lesions had formed during the active stage of the primary focus. As there was no anatomic evidence of hematogenous metastases to other organs, these single foci had developed either following superinfection from without or extension from the primary focus by intrabronchial spread. The histologic structure of these additional foci was identical with that of the primary focus.

In addition, effects of tuberculous infection in the subapical areas in chalky and calcified states are presented of unquestionably primary character with localized tuberculosis in regional lymph nodes which heretofore were considered as effects of a reinfection, especially with regard to their site and the localized intrabronchial spread. In 1 case such findings were bilateral.

Cases in which primary tuberculous infection remained restricted to the parenchyma of the lungs without evidence of spread to the lymph nodes formed about 10 per cent of our material. The incidence of true exogenous reinfections of the lung with the formation of a typical tuberculous complex of Ranke in the presence of an old, usually completely healed complex was also around 10 per cent of our material thus far examined.

Calcified structures that give x-ray shadows similar to older tuberculous lesions include phleboliths, parasites, and in many cases peculiar focal or diffuse bone formation of non-tuberculous origin (in the literature referred to as "osteoma"), calcification of small arteries in lymph nodes and occasionally, though rarely, nodular, focal calcification of bronchial cartilages, and, finally, calcification of the Botal's duct.

Several observations in children and adults point definitely to the possibility of superinfection regardless of whether the preceding infections were focal or presented by a typical complex. In a few of these instances the first lesion was not as yet healed. Individuals with healing lesions remain apparently exposed to new infections from without. A reinfection complex has been found, especially in such cases where the first complex had practically completely healed.

Discussion

DR EUGENE L. OPIE. I think that we are

particularly fortunate that a pupil of Ghon should have made this careful study of tuberculosis in this country, and I gather from what he has said that he has found the picture somewhat more complex than that which Ghon described. I assume this real or apparent complexity is in large degree dependent upon the fact that he has given more attention to older persons and, hence, has found lesions more varied than those that Ghon found in younger persons.

It is especially noteworthy that Dr Terplan has observed the increasing frequency of primary lesions with increasing age. The number of these lesions found in this country compared with their frequency in Prague is astonishingly small. I think Dr Terplan's figures are approximately 6 per cent below 6 years of age and about 19 per cent below 18. This represents a relatively small proportion when compared with the high incidence of tuberculin reactions in the larger cities of this country and of Europe. It is noteworthy that observations made in a rural district of Northern New York (Cattaraugus County) show that the percentage of persons who react to tuberculin at the age of 15 is approximately 16 per cent. Nevertheless, with the increasing age of adults the number of lesions increases greatly, so that many of these first infections are evidently acquired in late adult life.

Dr Terplan has emphasized the frequency of lesions of reinfection in adults characterized by the occurrence of "complexes" of different ages, one being calcified and the second caseous. Dr Terplan has described three such "complexes" of different ages. These observations introduce new difficulties in nomenclature. The usual form of reinfection in adults has been designated "adult type tuberculosis." When progressive it may be designated "phthisis." Dr Terplan has described a reinfection tuberculosis that repeats the characters of the first infection.

DR MAX PINNER. My main qualification for discussing Dr Terplan's paper is the fact that I am, as part of my editorial duties, thoroughly familiar with his work. It was indeed one of the great privileges of my editorial work to be a link between Dr Terplan and the publisher. On the basis of his published papers and from the demonstration to-night, I think it can be said without any question that this work represents the most complete and most thorough study that has ever been made on first and reinfection tuberculosis. It might be of some interest to ask what

the possible clinical and epidemiologic correlations are in regard to those facts that Dr Terplan has shown and that were previously not known. To mention just two of the important points—first of all, as Dr Opie has already emphasized, the classic picture of the primary complex, as described by Ghon and his co-workers, has become infinitely more complex. Ghon already has described multiple primaries on the assumption that they were simultaneous primaries. Dr Terplan's studies would indicate probably that some of these so-called multiple primaries are really complexes—to use his expression—which have occurred at different ages. It has been the classic teaching that the one lesion in tuberculosis which is entirely pathognomonic and invariably typical is the primary complex, with its typical parenchymal reaction and with the regular lymph node involvement. Now this picture undoubtedly has to be considerably revised. The fact that any later infection than the primary one would lead to a different type of histologic and possibly anatomic reaction was usually ascribed to a change in the reactivity of the organism caused by the primary infection. The demonstration that in the presence of a completely healed complex a new complex with the same histologic structure as a true primary infection occurs not infrequently probably means that the healing of the first complex is anatomically, bacteriologically, and immunologically complete, so that the body reverts to the same type of reactivity it had before the first infection. This seems to be well supported by relatively recent epidemiologic work in this country, particularly from some of the southern states. A number of reports have come out which show that in a rather astonishingly large percentage of children and young adults tested with tuberculin negative reactions to an adequate dose of tuberculin were found in the presence of roentgenologically demonstrable lesions that seem to be undoubtedly of a tuberculous nature. In addition, there have been an increasing number of reports to show that a person who has developed a tuberculin reaction may lose that tuberculin reaction, so that the previous statement, "once tuberculin-positive always tuberculin-positive," undoubtedly does not seem true any more, and we know that complete healing can occur.

Dr Terplan's studies show the anatomic substratum of this fact—that allergy may disappear and that the body may return to the same state that existed before the primary

infection Dr Esmond R Long, in studying this problem of waning allergy, has shown some quite convincing evidence that this occurs much more frequently in persons who do not live in contact with cases of open tuberculosis than in contact cases. In the open cases it is extremely rare that allergy disappears, in other words, continuous allergy is probably due to continuous reinfection.

I am sorry that Dr Amberson could not be here. I talked to him this morning about the paper and his idea about what he wanted to say in the discussion. He has permitted me to quote him regarding his studies on nurses in Bellevue Hospital. During the last ten years he has observed about 300 to 400 nurses who became tuberculin-positive after having been tuberculin-negative. A certain number of these cases developed clinically demonstrable pulmonary tuberculosis. Dr Amberson found—I think in accordance with some other workers—that, clinically and roentgenologically, no differential points could be found between the nurses who developed clinical disease immediately or shortly following a tuberculin-negative stage as compared to the nurses in whom tuberculosis occurred after they had been tuberculin-positive for some time. In other words, apparently neither clinical nor roentgenologic differentiation can be made between primary and reinfection tuberculosis. In no case has he been able to see lymph node enlargement in the primary infections. In no case, with the possible and doubtful exception of 1, was there any evidence of hematogenous seeding following the primary infection. It is interesting in this connection, however, that from other countries observations are reported which seem to tell a different story from Dr Amberson's studies. Hedvall and Mahros in Sweden have observed 151 cases that became positive. In 47 of these cases tuberculous lesions were demonstrable. Out of those 47 cases with clinical tuberculosis, 21 had a roentgenologically demonstrable primary complex. Out of a total of 19 cases of pulmonary tuberculosis in this group of first infections, 40 per cent were seriously progressive, which is an entirely different story from what is found in the Bellevue studies and in most of the other hospital studies in America. Most of these early cases in this country are not progressive if treatment is promptly begun.

Dr Long reported on the behavior of the primary infection in adults, and he found that some did and some did not show evidence of the primary complex—that is, a

parenchymal lesion plus lymph node involvement. It is interesting to know that all those in his series which showed lymph node enlargement were Negroes. It is probably important in all these apparent differences in the literature to consider the geography of the report and the type of epidemiologic development that exists under the particular conditions in which the studies are made. I do not know how homogeneous Dr Terplan's material is in regard to racial distribution. It is, of course, quite astonishing how heterogeneous it is in regard to the reaction to tuberculosis: primary foci without lymph node enlargement, multiple primary foci, repeated primary foci, and so on. In this connection it is probably important to emphasize how more and more evidence is coming to the fore to show what an important role the constitutional character of the individual plays in the reaction to tuberculosis. In experimental studies Dr Lurie showed that he was able to develop rabbits with high and low susceptibility to tuberculosis by inbreeding families. He has gone a step further, which might give us one clue to constitutional differences. He was able to show in these two families of different susceptibility that the reaction to nonspecific material is different. The histiocytic transport of foreign material is of a different speed in one family as compared to the other family of rabbits. This is possibly one of the constitutional factors which may help to explain some of the differences in the individual reaction both to primary and postprimary infection.

DR GEORGE G. ORNSTEIN (*by invitation*). I should like to ask Dr Terplan a question concerning the foci that he pointed out without any lymphogenous spread, such as foci of the primary phase of infection. We clinicians for a long time have been challenging our pathologists concerning whether or not they can differentiate between healed reinfection tuberculosis and the primary complex on the basis of histopathology. For a long time, differentiation of primary from reinfection tuberculosis has been based on studies of the longevity and age of the histopathology they have seen. Are they able to make such a differentiation?

From the clinical point of view, where we have had serial x-rays, we have been able to follow the primary complex from perhaps two or three weeks after infection for ten years thereafter, and the one thing we noted is that the method of healing varies with time. For example, the parenchymal component

of the primary tuberculous infection with deposition of calcium and bony formation is quite different from the healing in the corresponding lymph nodes, or vice versa, so that it seems to me if one is going to gage healing on the time element there will be a tremendous amount of confusion. For instance, if a child had died with a parenchymal component that calcified and a lymph node component that was caseous, we would look upon it as two different areas of age. I have asked our pathologist, Dr. Auerbach, whether he can differentiate a reinfection tuberculosis with healing and calcification simulating that of the primary from the primary complex, and I have never been able to get any definite answer that there are certain characteristic healings in the primary complex.

A question I wish to ask is: Inasmuch as there is no lymphogenous association with this reinfection that Dr. Terplan calls primary tuberculosis, is it not more logical to say the patient has had a focus of reinfection which has healed (and Dr. Terplan is noting for the first time that reinfection can heal like the primary complex) rather than that we are dealing with repeated primary tuberculous infections? In my own experience I can recognize by serial x-rays these reinfection areas of tuberculosis which have healed, and when I show these healed areas to the pathologists they have difficulty in differentiating them from the primary phase of tuberculosis. My feeling, therefore, is that when we gather sufficient material from these so-called multiple primary complexes without lymphogenous involvement they will probably be nothing more than healed reinfection tuberculosis. I would like to hear Dr. Terplan speak of that. I would also like to congratulate him on the tremendous amount of effort he has put in his valuable studies.

DR. KORNEI TERPLAN: I wish to thank all the speakers for their interesting discussion and their kind comments. In answer to the question of Dr. Ornstein: The histologic changes of focal lesions in each case show a great variety, as could be demonstrated even in children. There seems to be no question that the diagnostic criteria of Puhl as to the structure of the "reinfect" as compared with that of the primary focus cannot be accepted as conclusive. On this point I find myself in agreement with Dr. Opie and Freeman-Dahl and a few others.

A second point I believe we cannot answer in a definite manner is the part played by the

lymph nodes regional to the primary focus or to the postprimary lesions. They might remain, especially in primary infections, much longer in a cheesy-chalky state than a corresponding Ghon focus that has already been found to be firmly calcified or obsolete in these cases. In the so-called reinfection type, especially in more progressive cases, we have not infrequently seen distinct caseation in the bronchopulmonary and tracheobronchial lymph nodes and, especially microscopically, tubercles are found in many of them. But single foci, especially in the older encapsulated or even calcified state, cannot be diagnosed histologically as to their true primary or postprimary nature or by x-ray, as both will become calcified or even ossified eventually. There are, of course, many cases in which a larger area appears to be simultaneously involved, especially in the apical or subapical fields in the so-called reinfection type. On the other hand, we have proved this same distribution in a few unquestionably primary infections. In these cases, then, x-ray diagnosis of a so-called reinfection type sometimes might be misleading. In some cases, as we have tried to point out, single apical lesions have been found in relatively early stages of the primary focus. There was not the slightest structural difference between all of these lesions, including the primary focus.

I, too, have been much impressed by the great number of individual differences in this study, and I would hesitate to rely on any structural differentiation of focal lesions between first and the so-called reinfections. Single or a few scattered apical lesions could not be proved as hematogenous metastases, since in many of these cases tubercles were absent in those organs that could have been reached only by the hematogenous route. I am afraid I have not answered the questions of Dr. Ornstein in a satisfactory manner.

I have another question here: Is it possible to differentiate histologically the bronchogenic from the hematogenous lesion in the lung? Only in the early phases of hematogenous dissemination can the originally interstitial miliary character be recognized, especially from the small size of the tubercles usually surrounded by well-aerated tissue. In dealing with multiple, large, older or healed foci that very well might be hematogenous in origin, as in 1 case I showed here, histologically there is no way of distinguishing these from older single foci brought about by intrabronchial spread.

Special Article

THE ROLE OF THE DOCTOR IN THE DEFENSE PROGRAM

SAMUEL J. KOPETZKY, M D , New York City

CONGRESS has placed upon the statute books of the country a new law. The larger implications of this law are only commencing to be apparent to our people. The Selective Service Law in its larger connotations makes a new mosaic pattern of our life in this defense system.

The Selective Service focuses attention on the paramount concept that stresses the knowledge or awareness of each citizen as to what part he shall play in the unfolding drama of this program. It is, in fact, the duty of each to search out the place where his own qualifications can best serve his country. The exact part each citizen shall play may be elected by himself or the part may be assigned to him by his neighbors or co-workers.

This nation has met and quietly faced grave dangers to its existence in the past. In a world in which a revolutionary trend is gathering its destructive agencies, the very awareness of what must be done and how it shall be accomplished is the high sign that our nation is gathering its forces for its defense and its preservation and also to stop the spread of the encircling conflagration that would destroy liberty as we know and cherish it.

We have no illusions as to what is necessary. We have guns, ships, tanks, and airplanes. We know we need many more of all these essential weapons. We are handicapped by inherent barriers that have been erected by ourselves and which are mental attitudes produced by a decade and a half of national life pledged to an idealistic complacency. We have been led to believe that decency in itself, like virtue, was its own reward and protection. We held to the belief that this national decency was a defense against international lawlessness and that peace-loving peoples could remain apart and unembroidered. We have anxiously watched peaceful Norsemen, Dutchmen, Finns, Czechs, and other fine, peace-loving peoples ruthlessly overrun and overcome. The psychotic somnolence that led the mighty armies of France to think *defensively only* and not plan for offense against environmental

aggression points a lesson whose moral has not been totally lost to us.

We are most fortunate. We have been given time to prepare, "to trim ship," to make ready for the approaching storm. Our broad acres are fruitful and produce our food requirements, our rich mines give us the metals from which our arms are forged. The busy hands of our workers fabricate the essential supplies needed not only by our civilian population but also by our armed forces. To accomplish the common purpose that the defense program sets, demands the united efforts of all elements in our population. We have just passed through a phase of obstructive barriers raised by strikes. I believe this barrier has about passed. During the recent weeks any intelligent observer could have sensed a trend in current domestic events which showed that American public opinion was being exasperated by this showing, and organized labor itself seems to have begun to adjust matters more in conformity with the desire of our people for a united, unhindered production effort. Our President has solved the issue by the Proclamation of Full Emergency. We can, I feel sure, look forward now to seeing ownership, management, and labor all doing their full share, each contributing a sacrifice toward the common objective—the preservation of the "American way of life."

For us, the doctors of the nation, there also must be sacrifice. This sacrifice must be coupled with service. The organized medical profession must play its part in this defense program.

In this state we have placed our entire resources behind the defense program. Each county society will do its allotted share in this task of concerted effort to serve the community. We have manned the medical section of the Selective Service Administration. Thousands of our colleagues are giving hours of painstaking work, selecting the vigorous among our youth to serve in the armed forces of our country. When it is comprehended that the doctor has no spare time, has no part of his day when he is "off duty," it must be realized what this type of patriotic contribu-

Read before the Medical Society of the County of Monroe May 29 1941 Rochester New York.

President Medical Society of the State of New York.

tion entails—gladly given, gratis, to serve our government. To a large measure, too, we have staffed the medical sections of the army induction stations located in this state. Others among us are already in the field as officers to our armed forces. During the next year about 5,000 medical officers will be needed for the expanded army alone. The organized medical profession of this state will furnish its quota.

Our leaders of thought, the teachers on the staffs of our great institutions of learning and research, are foresighted enough to plan so that there shall be no interruption of the even flow of educated, highly qualified medical men into our community life to carry on the magnificent medical traditions in vogue here. What need have I to dwell upon details before a medical audience? Not capital, nor management, nor labor alone has problems that the clouds of hatred and oppression abroad have raised and intensified here. Nor do the repercussions from the strife abroad leave any sector of American life unaffected. Nor are we, as doctors, unaffected.

Insidiously creeping outward in an ever widening circle from its central pool of nazism is that hideous thing termed *racial hatred*, with its accompanying component of religious persecutions. This comes from the fair land that was once Germany—the breeding ground whence sprung poets and painters, musicians and philosophers, master craftsmen and medical solons. Nor are we unaffected, even though we are uninvaded. As doctors we all know and comprehend the nature and the manner of contagious and communicable diseases, but fewer of us apprehend the nature and the manner of “mental contagion.” You will comprehend what I mean by mental contagion when you recall that the publication of one type of murder is almost invariably followed by others in its imitation. A few years ago a young student, leaving a suicide note containing his belief in the futility of life, died by his own hand. He became the model that a few others followed, mentally infected by the heinous virus of his example. None of us these days can be too sure of our mental reactions to the virus of racial hatred, the incessantly recurring waves of which reach us from the poisonous cesspool of its origin. Petty annoyances excite reactions that, because of this impact, we do not handle with the rationalization and surety we are wont ordinarily to employ. Specific minor irritating factors become magnified beyond their actual worth, because this incessant impact

from abroad prevents sane, healthful mental attitudes on our own part. I am telling you all this because we as doctors have another and a different obstructive barrier to overcome. The handling of this question needs our healthiest thought. No spirit of racial hatred must intrude upon a process of clearly thinking the matter through to a logical conclusion.

There are in this state, in addition to our native sons who are doctors, over 2,500 medical men of foreign extraction, driven by persecution from their native lands. They have located in various parts of this state because of its liberal license provisions.

These men must be integrated in our medical defense program. Not to do so will work an undeserved handicap upon our native medical men. For our own native medical men to give up their private practices and hospital positions at the call of our government and leave these newly arrived physicians *at home* is something I should like to see avoided. I have reported upon this phase of our program to the national authorities and to the National Committee on Medical Preparedness of the American Medical Association. The national authorities imply that this is mostly a local problem since, by far and large, most of the physician-refugees have congregated in our state. They are not here because they desire to stay in the congested eastern section of the country. Many of them have told me of their entire willingness to go to any place in the United States where they could serve the community in a medical capacity. The provision of the licensing laws of most of the states is the handicap they cannot surmount, nor is a provision requiring full citizenship an adequate answer to the problem. To do this would create undreamed of conditions and trouble for organized medicine.

Under present conditions I would not abate one step in our open-handed hospitality. Still, I believe the situation calls for thought and action.

Since this is a state problem, let us handle it through our state agencies. Let us cease wishful thinking and adopt a positive position. Let us initiate remedial action.

A proper public opinion upon this question is the first requisite. There should be a general public comprehension that these men will take their places in our ranks in this defense program and they too will serve our government, which provides the political atmosphere that tolerates and encourages

the stranger to feel at home when he comes with clean hands among us. All of us, or our ancestors, were at one time "strangers" here. Our authorities should survey their capabilities, have in mind their mental equipment and qualifications, and fit them into the mosaic of the medical pattern of our defense forces. I do not advocate that these men, with their inherent nostalgic tendencies, ever be assigned to key positions in our defense mechanism. But some place where they may serve must be found for them. This should be done so that when this emergency shall have passed—as all mundane things do—they and the rest of us will again start upon our civilian medical practice with an equal chance and an equal opportunity—the American unhandicapped because his government called him to Federal service, and the foreigner not given an advantage because he is prevented from serving and forced to stay at home. If left at home, he meets his returning American colleague from the advantage point of security, while the American must begin all over again to pick up the threads and develop his security from scratch—the foreigner meanwhile already far along the track toward the commonly sought goal. I advocate putting the refugee-physician into the mechanism of our medical defense program not only because he should in this way repay the free gift of American hospitality but also because I do not want to see the American doctor handicapped—because while he serves, his foreign colleague profits, since the high privilege of service is denied to him.

The leadership of organized medicine in all these efforts has been carefully selected. Confident in this leadership, each individual member of the medical profession has his individual task. The medical professional man now realizes that it is not what he personally may want to do that counts but it is the carrying out of the tasks set for him by those he has elected to be his officers. Thus, I summarize the patriotic contribution that each of us will be called upon to make. In its essence this will necessitate sacrifices on our part.

There are four recent historic happenings that are so significant that I believe they signalized a definite epoch in American history. First, the re-election of a president for a third term, second, the passage of the National Guard Law, which took the National Guard beyond the borders of the state for field service for a year or more during a time of peace. As part of this particular piece

of legislation, medical reserve officers lost the privilege they heretofore have had of refusing to accept assignments to full military duty in peacetime. Third, the passage of the Selective Service Law during peacetime, making certain that our man power undergoes compulsory military training. Fourth, the appointment of a civilian coordinator to integrate all manner and means of our citizenry in an organized coordinated defense unit, something that we have never before had in this country in times of peace or war.

Surely, the enactment of this legislation should make us aware, if we needed any reminders, that we are passing through historic changes, even though no gun has been fired in combat by any American unit. All this I had written before the presidential proclamation of May 27. Now it is official. We are in a full emergency status.

Emanating from this legislation, changes are impending in which we, the doctors, are inherently interested. Selective Service in the New York City area alone has examined through the eleventh quota call of the Army (up to May 9, 1941) 87,085 registrants. Of these, 22,445 are classified for limited military service. The figures will probably be duplicated from the Albany headquarters in its section of the Selective Service medical examinations. The Federal government has already set up a National Commission on Rehabilitation under the chairmanship of a New Yorker, Dr. George Baehr. Plans are being discussed as to how this remedial therapy should be devised. There were efforts made by the Federal administration to enlist the aid of ancillary medical services—the Red Cross, the welfare agencies. The use of educational propaganda by the press and radio was enlisted and the good offices of the American Legion asked.

All these agencies, cooperating wholeheartedly to induce those classified in the 1-B category voluntarily to seek remedial therapy, were put into force in one area in New York City. Not much progress seems to have been made. Recently, the Long Range Planning Commission for a Health Program, under the leadership of Mr. Muller, took cognizance of the problem, and this commission has appointed a subcommittee to study and report upon the problem. I have confidence in this commission. At some subsequent time and upon another occasion, I shall tell the profession how this commission is earnestly functioning. Here, I desire to pay a deserved compliment to Dr. Kaiser,

a member of that commission from the Monroe County Medical Society

But, to come back to the question I am now discussing—the rehabilitation of these many men. Sensing that voluntary submission to remedial therapy would not be a success because these men had adequate medical service at their doorstep during all their years of affliction when they were in civilian occupations, I felt that they would not seek medical aid voluntarily now, with the motive of seeking it to be put into full army service. Here again was demonstrated the truism that organized medicine has so often enunciated—namely, that for a certain percentage of the population, even though the tender of medical service were brought actually into their laps, these people would not avail themselves of it of their own free will, and the reformers' incessant cry for more and more medical services to the whole community would actually not better to any great degree the health record of our community. In March of this year, commenting upon this topic in one of my periodic bulletins (*S S Medical Bulletin* No 3, Headquarters, New York City Administration) I wrote

"Educational campaigns are not enough to make the obvious remedy to solve the problem practical. The concept that every citizen has an obligation to perform his military duty should be strengthened. A law which makes it compulsory for the citizen to perform a year's duty in the armed forces of the country should be broadened to prevent remedial physical defects from deterring men from carrying out this obligation of citizenship."

I suggested a *provisional induction* into the Army and the immediate transfer of these men to military hospitals for curative therapy. After a period of convalescence during which medically supervised body building and strengthening would be undertaken, there then should follow full induction into Army service in the usual way.

This remedial therapy should be so arranged that each registrant would be given the *right to elect* the choice of having this remedial therapy done by his own private physician in the usual manner of private practice. If he failed to elect to have it done by his own physician, then the Army surgeons would perform the required medical service. The majority of these men are not the patients of privately practicing physicians. Thus, no actual infringement of private practice would result. I should have the compulsion apply

only to the taking of steps to procure the necessary measures of therapy to effect a cure. The manner of its performance and by whom it would be done I should like to see made elective, thus maintaining for the registrant the principle of free choice of his physician even in this category of medical service.

The problem is still undetermined by the national authorities. On May 28 I noted a press release from General Hershey in which he intimated that the army would undertake remedial therapy for the men classified in Class 1-B.

To us in the organized profession, this decision should be satisfactory, for when and if the present emergency is passed and the army is demobilized, the military hospital will also be demobilized, and its staff of reserve officers, now manning it for the duration of the emergency, will have to be returned to civilian life. I much prefer to see this agency undertake the task rather than almost any other in the Federal medical setup. Every one of the others are permanent features of our Federal medical setup, and all of these have an inherent tendency to build themselves into larger and more permanent units. I should severely deprecate any incentive, under the guise of our defense program, feeding nutriment to Federal or state agencies, other than those connected with our temporarily expanded armed forces, to give them permanent stability which would carry them over into our civilian medical practice, in the eventually ensuing era of peace, to become fixed in our medical scheme of things and aid in destroying medicine as we know it.

This brings up the question of adopted policy in our State Society. It is easy to be swept along with the momentarily popular swing of the tide. America is making a serious and strong effort to bring about a defense mechanism that will protect and preserve the American way of life. We should fight, as our forefathers fought, to keep all our liberties without any infringement or curtailment whatsoever.

Obviously, under the stress of wartime exigencies, certain patterns of our activities must perforce change so as to meet the realistic situation with which our people are confronted. But in planning and executing these manners of procedure to meet an instant need, let us so plan that we do not undermine the very democracy and the way of

life we are striving to preserve Let us build no Franksteins!

It is essential for us to remember that in meeting the requirements produced by the present emergency the *way be left wide open* so that when the emergency is passed we can easily return to our normal methods and manner of living This is essentially desirable for those of us who are doctors Our way of life has produced a health record among the people we serve second to none—anywhere in the world There may be debatable ground on the distribution of medical care, but the health record, as it is scanned over the years, is not only a source of pride in accomplishment but is a level of achievement which it should be ours to preserve and, if possible, make even better Therefore, we, as physicians, must take the yardstick of *quality of medical care*, measure each and every possible proposition advanced in the name of the National Defense Program, and see to it that, however much necessity exists because of instant situations, this shall not break down the employment of our "constant yardstick." It should be ours to so plan measures integrating community medical care in the Defense Program that they shall carry within themselves their discontinuance or dissolution when the present emergency is passed and has become history

The role of the physician in the present emergency can be summed up by saying that he is the teacher of habits conducive to good health in the young, he is the means of caring for the incidental, casual illnesses that happen

during the period of growth, he is the help and resource of the injured in industry, and he protects the community health through sanitation and hygiene

At present, a large number of our medical men are serving in the Selective Service Administration, selecting the healthy, vigorous types of our young men for induction into the armed forces of the country But the doctors from among us, actually go with them into the camp, and on the ships of war, into the garrison, and into the field Also when battles are fought, they go with the soldier into the front lines In all these stations, they are present where they may be of service and where their medical knowledge can be of use

A sick man is a liability in civilian life To make the output of industry reach the peak of its possibilities, workmen, too, must be kept healthy In the armed forces a sick soldier is worse than no soldier because it takes two other soldiers to look after him.

There is no angle in the community life or in the military life of the nation where the doctor has not his proper and his fitting place It is the particular job of organized medicine to furnish the doctor for this important role in the national defense

The role of the doctor in the defense program may be said to reach into every home in the land, into every industry working for the defense program, into every school and college of the land, into every ship, warplane, regiment, or detachment and into every post of the far-flung military bases of our country

OFF HIS HEAD AGAIN

An inmate at an asylum after fifteen years of confinement was being released On the day of the release, his brother had come to the institution to call for him. However, the inmate was at the mirror and shaving When the intern informed him that his brother was downstairs waiting to take him away, the inmate replied that he had to finish shaving and for his brother to wait Ten minutes later the superintendent came and asked the inmate to leave, that his brother had a taxi downstairs and the meter was mounting the cost The inmate replied that after fifteen years of waiting to leave the place his brother could wait a few more minutes He went back to his shaving and within twenty minutes his brother finally came after him and the inmate said to wait another minute or two

Before turning back to the mirror, the looking-glass fell to the floor With his razor raised, the inmate stared at the blank wall "Imagine, after 15 years of shaving, on this day, I have to go and cut my head off!" he remarked!

DR. BANTING'S PAINTINGS

Three paintings by Sir Frederick Grant Banting, codiscoverer of insulin who was killed in the crash of a military plane in February, were among the outstanding works shown at the annual exhibition of the New York Physicians Art Club for the benefit of the British War Relief Society

The fact that Sir Frederick was held in high esteem as painter of the Canadian scene came as a surprise to many of his medical colleagues in the United States who have long regarded him as one of the foremost figures in the profession. The titles of the pictures are "North Shore of the St. Lawrence (Quebec), oil, "Craig Harbour" (Ellesmere Island), sketch, and "Mary Lake" (Canadian Rockies), sketch.

The New York *Herald Tribune* commented "The paintings are of scenes in Canada and provide a tangible reason why Sir Frederick was known as an excellent amateur artist as well as a research scientist They are not the conventional works of an untrained artist, but on the other hand, they show no mad desire to create a new form of art They are just different "

a member of that commission from the Monroe County Medical Society

But, to come back to the question I am now discussing—the rehabilitation of these many men. Sensing that voluntary submission to remedial therapy would not be a success because these men had adequate medical service at their doorstep during all their years of affliction when they were in civilian occupations, I felt that they would not seek medical aid voluntarily now, with the motive of seeking it to be put into full army service. Medical News

County News

Albany County

Dr Frederick A. D. Alexander, director of anesthesia and gas therapy at Albany Hospital, spoke on "Shock" at Albany College of Pharmacy on June 25 for the county society. Dr Arthur M. Dickinson led the discussion.

Twenty-nine graduates of Albany Medical College received their degree of Doctor of Medicine at the one hundred forty-sixth annual commencement of Union University on June 9 in Schenectady, and immediately fifteen of the new doctors were presented with commissions in the U S Army.

Dr Arthur J. Bedell received the Honorary Degree of Doctor of Science from Hobart College, Geneva, New York, at their commencement on May 26 and from the University of Colorado, Boulder, Colorado, on June 9.

Chautauqua County

If there are any physicians in the county who might be viewed as receptive candidates for coroner, they failed to announce themselves at the meeting of the county society, held on June 19 at Shorewood Country Club, says a dispatch to the *Buffalo Courier Express*. The subject was discussed at the meeting, but nothing came of it. "Plenty of disagreeable work and little money go with the job," one physician remarked after the meeting.

It was pointed out that Dr. Luke H. Boyd, of Bemus Point, elected coroner two years ago, evidently had enough, as he is not to be a candidate for re-election. Dr. George E. Blood, of Fredonia, now in his twenty-first year as coroner, is quoted as saying nothing could induce him to take another term.

With two impending vacancies, there has been talk of naming physicians for the two Republican nominations, equivalent to election, but the big problem appears to be to induce them to run.

The meeting of the county society followed a 1 o'clock dinner, with forty-three in attendance and the president, Dr. E. J. Kelly, Jr., of Jamestown, presiding. The main talk was given by Dr. A. J. Beams, of Cleveland. He spoke on some new methods of diagnosis and treatment of intestinal diseases.

Chemung County

The county society heard two addresses at a dinner meeting at the Elmira Country Club on June 12.

Dr. L. Wing, associate professor of obstetrics, Cornell Medical College, spoke on "Recent Developments in Obstetrics." Dr. J. King, neurosurgeon of New York and Bellevue hospitals, spoke on "Head Injuries."

Essex County

The semi-annual meeting of the county society met at the Deer's Head at Elizabethtown on June 3. Dr. Rudolph Ruedemann, dermatologist at the Albany Hospital, was the speaker.

Herkimer County

Dr. V. M. Parkinson, superintendent of Pine Crest Sanatorium, told of recent improvements in the treatment of tuberculosis when he addressed the county society at the Sanatorium at Salisbury on June 17.

Dr. Parkinson said that a renewal of use of pneumothorax with a new instrument that locates the seat of the disease has proved much more beneficial. Years ago when the pneumothorax was first used the desired results were not obtained, but this situation has been reversed.

The doctor showed x-rays of some patients who had several ribs removed to collapse their lungs and of other older methods of treatment.

The next meeting will be in October.

Montgomery County

Supreme Court Justice Christopher J. Heffernan gave a highly informative talk at the semi-annual meeting and dinner of the county society held at Canajoharie on June 11. His topic covered several fields of medical jurisprudence and stressed that the legal and medical professions have a duty to each other and to the public—the duty of bringing the best thought of both to bear on the problem of revising the system of penology to the end of creating an accepted definition of insanity and a clear understanding of the difference in the degrees of homicide.

The professions of law and medicine, while they have become divided in the course of time, were not far apart in the beginning, when the soothsayer who read the entrails of slaughtered animals made laws for men to follow, both for his personal good and the good of society. Now, the judge by his words may bring pain to those who are brought before him, while it is the physician who comes to the homes where disease and death have entered and by his skill and courage brings hope out of despair and life from the destroyer.

We have a wrong penal system and must look to the doctors for help. There will probably be no immediate change, but 100 years from now men will look back upon the present system with the same revulsion as we now look upon the penal system of 100 years ago, when 160 crimes were punishable by the death penalty. Punishment is necessary not only to deter the criminal who has erred but also to deter the one who has never done wrong but who, without the fear of punishment, might be inclined to do so.

The system of punishment is irrational in that first offenders are confined with morons and recidivists. Students of mind and body realize that there is much waste and futility in it all, and we look to the medical profession to revitalize the tissues of the law. The life history of a man condemned to the chair marks a course from reform schools and state prisons to, finally, the death penalty. Such a man seems to have been doomed from the beginning.

Definitions of homicide and first and second degrees of murder are none too clear. First-

degree murder is defined as a deliberate design and intent by one person to bring death to another, while second-degree murder is defined as killing with intent but no deliberation. The difficulties of the law arise in determining what is meant by deliberation and premeditation, since the human mind and brain are so made that it is not necessary to show the law that weeks, days, or even minutes have elapsed during which the deed was planned or premeditated. It is all too vague. There can be no intent unless there has been a choice, and there is no choice unless there has been an emotion so great as to sweep the mind from its moorings. Too many times jurors are confused by cunning words that only cloud the difference between first- and second-degree murder, and scores have gone to their death because of this confusion.

Mental irresponsibility or insanity was not accepted as a defense at one time. There came into the vocabulary of law what was termed as the "wild beast defense"—a state of mind during which a man lost all sense of right and wrong and for a moment became like a beast. Then came the issues of whether a criminal knew the specific act he committed was wrong, whether he knew right from wrong as an abstract proposition, or whether the conditions which caused the act were such as to justify it. There is a twilight zone between sanity and insanity. It is all vague. The medical profession must combine with the legal to frame a definition.

At the close of the meeting, upon motion of Dr. E. C. La Porte which was carried unanimously, Dr. Henry C. Young, Hagaman, New York, who has been a faithful member of the county society for fifty-three years, was elected to honorary membership.—*Reported by Roger Conant, M. D., Secretary*

Nassau County

The following committee chairmen have been appointed for 1941-1942: entertainment, Dr. Walter C. Freese, Baldwin; legislation, Dr. Eugene H. Coon, Hempstead; maternal welfare, Dr. G. Borden Granger, Rockville Centre; medical economics, Dr. Stuart T. Porter, Floral Park; professional advisory, Dr. Everett N. Whitcomb, Port Washington; public health, Dr. John M. Galbraith, Glen Cove; public relations, Dr. Wilfred M. Post, Williston Park; and scientific sessions and postgraduate education, Dr. Dwight T. Bonham, Hempstead.

New York County

"In its brief period of existence the Committee on Medical Preparedness of the Medical Society of the County of New York has rendered significant service to the defense program," says the *New York Medical Week*. "Organized less than a year ago, it has compiled an enormous amount of essential information about the physicians and hospitals of this district. It has kept seventy local Draft Boards and eight Medical Advisory Boards supplied with competent professional personnel and has procured qualified specialists to serve on Army Induction Boards in the metropolitan area.

"In a sense every loyal physician is a member of the Committee on Medical Preparedness, for, in the latter's own words, 'the cooperation of the profession is the fundamental basis for the

effective operation of the national plan.' So far this cooperation has been forthcoming in good measure—most of the 7,000 questionnaires sent out by the Committee have been returned completed. Physicians who have not yet filled out their blanks are urged to do so without further delay.

"The Committee has made good use of the information received so far. Besides supplying necessary medical assistance to the Selective Service System, it has listed all physicians according to age groups and availability for various types of duty. It has classified some 800 or more surgeons according to experience and ability and is now about to make similar classifications of otolaryngologists, industrial physicians, and other specialists. In spite of the enormous amount of detail involved in these tasks, it has found time to study general aspects of the Draft affecting the medical profession and to keep the latter informed of policies and practices in which its interests are involved.

"This is an unusual record of accomplishment, challenging the highest standards of patriotic action. The Medical Society of the County of New York is deservedly proud of the Committee on Medical Preparedness and its contribution to the national defense."

Dr. Alfred M. Hellman, president of the county society, has sent the following letter to Mayor LaGuardia, director of the Office of Civilian Defense:

"Honored Sir

"At a Special Meeting of the Comitua Minora of the Medical Society of the County of New York, held on May 22, 1941, it was voted to offer to you, as United States Director of Civilian Defense, the full cooperation of the Medical Society of the County of New York in any way you may care to use the facilities and membership of our organization in the furtherance of your plans for National Defense.

"We would all like to be of service to you and our country in this emergency, in any way desired."

The New York Roentgen Society has elected the following physicians as officers for 1941-1942: president, Dr. Douglas Quick, vice-president, Dr. Eric J. Ryan, secretary, Dr. Paul C. Swenson, treasurer, Dr. Maurice Pomeranz, member of the executive committee, Dr. Henry K. Taylor, retiring president.

Dr. C. Ward Crampton has received the Award of the Silver Buffalo for "distinguished service to boyhood" by the Boy Scouts of America. The award is made on the basis of noteworthy service of a national or international character, outside of line of regular duty, to boyhood, either directly to or independent of the Boy Scouts of America.

Dr. Crampton was for twelve years director of physical education and hygiene, Department of Education in the Schools of New York City. He was founder and president of the Anstogenic Association. For over seven years he has written a page on "Physical Fitness" in *Boys' Life* magazine. Dr. Crampton organized and was first chairman of the Greater New York Boy Scout Committee, which became the Greater New York Boy Scout Foundation.

Onondaga County

Dr J G Fred Hiss, professor of clinical medicine at the College of Medicine, Syracuse University, has been placed in charge of the National Youth Administration Medical Program in upstate New York, according to announcement in Albany.

He is chairman of a subcommittee of the Council Committee on Public Health and Medical Education of the State Society, especially assigned to working with youth groups. His work to date on this committee has been mostly with 4-H groups.

Ontario County

Dr C Harvey Jewett entertained the Canandaigua Medical Society at his cottage on the West Lake Shore on June 12. Dr Charles J Bobeck read a paper on "Cardiac Arrhythmias."

Orange County

Dr John W McKeever was appointed chairman of a committee to draw up a new constitution and bylaws for Newburgh Bay Medical Society at its annual dinner and organization meeting in the Palatine Hotel at Newburgh on June 10.

A sound picture in natural color on hunting and fishing in the Catskills and Hudson County, through the courtesy of M D Cadman, pharmacist and sportsman, featured the meeting.

Putnam County

At the annual meeting of the county society on June 4, at the Gypsy Trail Club, Dr John T Jenkin, of Lake Mahopac, was elected president for the next year. Dr Alexander Vanderburgh, of Brewster, was chosen vice-president and treasurer, and Dr George H Steacy, of Lake Mahopac, became secretary. Censors are Drs Robert S Cleaver, of Brewster, Ralph M Hall, of Cold Spring, and William P Kelly, of Carmel. Dr Henry W Miller, of Brewster, was re-elected state society delegate.

The meeting was the occasion of a joint scientific session and dinner with the Putnam County Nurses' Association. Thirty-five members of the association were present and were welcomed by Dr Cleaver, retiring president. Responses were made by Mrs Mildred Knapp, president, and Miss Hetta Alexander, secretary, of the Nurses' Association, and by Mrs Marie Hart, district state supervising nurse.

Speakers at the scientific session were Dr Camille Kereszturi, assistant pediatrician at Vanderbilt Clinic, whose subject was "Progress in Pediatrics," and Dr Eugene Bard, of Columbia, who spoke on "Progress in Dentistry." Among those taking part in the discussion was Dr Langmuir of the Westchester County Department of Health.

Dr Donald W Ruchie, of Croton Falls, appealed for volunteers as blood donors in connection with the National Defense Program.

An immediate and specific result of this first gathering of county doctors and nurses is the establishment at the Mahopac Emergency Hospital of a nurses' registry, where a list of graduate and practical nurses, available for duty and on public call will be kept for the immediate convenience of physicians and the public.

Richmond County

The annual dinner of the county society was held on Wednesday, May 7, at the Meurot Club, St George, Staten Island. A large number of members attended the affair. The guest of honor was Dr Nathan B Van Etten, president of the American Medical Association. Dr J J Goller and Dr O M Race were in charge of the arrangements for this dinner.

Saratoga County

The county society held its June meeting at the research building at the Saratoga Spa on June 19.

Dr Robert Linton, Boston, spoke on "The Diagnosis and Treatment of Peripheral Vascular Disease." Dr Linton is instructor in surgery of Harvard Medical School and surgeon on the staff of the Massachusetts General Hospital.

Dr Frederick G Eaton was elected president of the Saratoga Springs Medical Society on June 12. Dr Eaton succeeds Dr H Dunham Hunt.

The election followed a dinner at Riley's Lakehouse. Dr Lyle Sutton, Albany, discussed endocrinology.

Other officers elected to serve with Dr Eaton were Dr Robert E Rockwell, vice-president, and Dr John A. Esposito, secretary and treasurer.

Steuben County

Members of the county society dined at the Veterans Administration Facility at Bath on June 12 and held their meeting at the Facility following the dinner. Dr Joseph Boch of the Facility Hospital medical staff discussed the treatment of asthma, and a sound and color film on otoscopy in inflammations was shown.

Westchester County

About 130 members of the county society, their wives, and guests attended a dinner dance on June 14 at Westchester Country Club. The event replaced the society's annual dinner. Dr Reginald A. Higgins, of Port Chester, president of the society, was toastmaster.

Dr Samuel J Kopetzky, president of the State Society, urged physicians to be on the alert for new proposals that may be put forward now in the defense program. He warned that the American way of life may be endangered by changes sought in the guise of "defense" in that way of life.

Another speaker was Dr Benjamin P Watson, director of obstetrics at Sloane Hospital for Women, New York City. He discarded his topic, "Medical Controversies of Yesterday and Today—A Contrast," and confined his talk to a recitation of humorous Scotch stories.

The Yonkers Academy of Medicine held its annual meeting at the Hudson River County Club in Yonkers on May 21. Dr Barclay Parsons, attending surgeon at Presbyterian Hospital in New York, presented a paper on "Side Issues of the Thyroid Problem." In the executive session, Dr Virginia Minervini was elected president of the Academy, succeeding Dr Wilbur W Stearns. Dr Romeo Roberto was elected vice-president, Dr Jacob Kertzman, second vice-president, Dr Angelo R Onorato,

No food (except breast milk) is more highly regarded than Similac for feeding the very young, small twins, prematures, or infants who have suffered a digestive upset. Similac is satisfactory in these special cases simply because it *resembles breast milk so closely*, and normal babies thrive on it for the same reason. This similarity to breast milk is definitely desirable—from birth until weaning.

A powdered, modified milk product especially prepared for infant feeding, made from tuberculin tested cow's milk (casein modified) from which part of the butter fat is removed and to which has been added lactose, vegetable oils and cod liver oil concentrate

One level measure of the Similac powder added to two ounces of water makes 2 fluid ounces of Similac. The caloric value of the mixture is approximately 20 calories per fluid ounce.

recording secretary, Dr Edward J Maychick, corresponding secretary, and Dr A. A. Morrone, treasurer. New councilors elected were Drs George B Stanwix and Eugene F Kelley.

The White Plains Medical Society held a regular meeting on May 13 at the Westchester Hills Country Club. Approximately thirty-five members were present. The Sports Committee, under the chairmanship of Dr Arthur S Strauss, reported that there would be three golf matches held in June, July, and September. Major Edward H Marsh, of White Plains, who is now attached to the Surgeon's Office at the Headquarters of the Second Corps Area on Governors Island, was the speaker of the evening. The subject of his talk was "A Doctor Looks at Mobilization." He gave an interesting picture of the new soldier's routine from the time of receiving his questionnaire to the time he becomes a regular Army man. Following the meeting, a collation and entertainment were enjoyed.

The New Rochelle Medical Society held a regular meeting on May 12 at the New Rochelle Hospital. Dr David Sloane, of Larchmont, presented a paper on "The Role of the General Practitioner in the Treatment of the Crippled Child."

Yates County

The Lake Keuka Medical and Surgical Association met on July 10 and 11 at the Keuka Hotel

on Lake Keuka. Some of the speakers and subjects were as follows:

Dr Louis Faugeres Bishop, Jr, Bellevue Hospital, New York City "Senile Heart, Observations, Prognosis and Management."

Dr Lee Adrian Whitney, Genesee Hospital, Rochester "Modern Management of Fractures."

Dr John W Norcross, Lahey Clinic, Boston "Haematology from a General Practitioner's Point of View."

Dr James E King, University of Buffalo "Pruritus Vulvae."

Dr Raymond J Pieri, Syracuse University "Direct Supra-Vesical Caesarian Section" (motion pictures).

Dr William Johnson, St Jerome's Hospital, Batavia "Reminiscences, Serious and Other wise—1892 Model," with comments by Dr A. A. Aaron, University of Buffalo, on "1912 Model."

Dr Donald Guthrie, Robert Packer Hospital, Sayre, Pennsylvania "Pre-Operative Care of Toxic Gout Patient."

The summer medical meeting of the Lake Keuka group draws from all parts of New York and adjoining states. Leading physicians and surgeons from New England, Pennsylvania, Ohio, and the midwest, in addition to representatives of ranking institutions in New York State, attend each year. Dr Leon M Kysor, Horrell, is president, Dr Noble Chambers, Syracuse, vice-president, and Dr Virgil H F Boeck, Dundee, secretary-treasurer.

ACE'S PART IN THE GRAND SLAMS

"In my opinion over 50 per cent of the crashes in aviation can be attributed to the pilot, and generally poor judgment on the part of the pilot will cover many mishaps," Dr Frederick Ceres, Captain, Medical Corps, United States Navy, Pensacola, Florida, declares in an article on "Aviation Medicine in the United States Navy," in the first issue of the new bimonthly publication, *War Medicine*.

"It is my belief that high physical and mental fitness will produce an alert, clear mind and quick reactions," the Captain continues by way of explanation of his declaration that one of the most important functions of the Aviation Medical Section in the Medical Department of the Navy is the maintenance at a high level of physical fitness of naval aviators.

He says that "the primary mission of the Aviation Medical Section of the United States Navy is to keep as many aviators flying in as many airplanes as are available as many days as possible. This is aviation medicine."

THE OTHER HALF

The other half do not come out!

The other half lets George do it!

The other half has the same problems, are benefited by the same actions, but, like the proverbial vest, let the pants and the coat do all the work while they get all the gravy.

The other half is indeed the other half. Not a separate part of the medical profession, not someone whose actions and attitudes do not affect the others.

Do you belong to the other half? Are you among those who never attend meetings? Never participate in society activities? Never help in solving problems?

If you are, snap out of it. Do yourself and this society and the profession to which you are privileged to belong some good. Attend the meetings. Hide not your light under a bushel. You have good ideas, sound plans, and a vital interest in what happens. Attend meetings—*Exchange*, quoted in *Westchester Medical Bulletin*.

ROUTINE IS IMPORTANT

There is hardly anything worth mentioning that is not enhanced by even the slightest semblance of "routine"

If we want to go as far as being technical about the matter, actually there are few things, organizations or individuals capable of existing without more or less routine. It may be affected or forced upon us. It is there, however, call it system or details or whatever you choose.

To some it becomes a drudgery. To others, it is a foundation upon which they build.

Look about you, analyze your own day, and you find a specific routine. It may break down, time and time again, but you go back to it as often as it may be interrupted.

It is not at all strange, therefore, to find that our hospitals and sanitariums are the best examples of the value of routine. Check the activities of a hospital or sanitarium. The patient is admitted, undergoes a strict examination, is placed under observation day and night, is treated and nursed methodically, and even in a period of convalescence is encouraged to repeat some daily formula until fully recovered.

Routine in the institution is evidence of sincerity in providing every possible aid for the benefit of the patient. The amount of routine work covered and its extent of efficiency should be at least one yardstick for evaluating the hospital or sanitarium recommended for your patients.

WEST HILL

West 252nd St. and Fieldston Road
Riverdale-on-Hudson, New York City

For nervous, mental drug and alcoholic patients. The sanitarium is beautifully located in a private park of ten acres. Attractive cottages, scientifically air-conditioned. Modern facilities for shock treatment. Occupational therapy and recreational activities. Doctors may direct the treatment. Rates and illustrated booklet gladly sent on request.

Woman's Auxiliary

To the Medical Society of the State of New York

"AS LONG as there are postmen, life will have zest."—*William James* Hence, we are printing excerpts from a letter reporting the highlights of the A.M.A. Convention.

Dear Sara

Where were you this Convention? I went out on the sleeper Saturday and arrived at the Carter at 7 30 A.M. Sunday. Having somehow slipped under the dignitary line last year and been invited to the tea Sunday afternoon and the dinner Monday night, I thought it followed that I could go this year. But I guess those things aren't "crashable." So, I can't tell you a thing about the tea that was held at the Women's City Club for the National Board of Directors honoring Mrs. Holcombe.

Monday noon I found the familiar faces of most of the New York delegation at the luncheon at the Petit Cafe in the Carter. There were fourteen of us. Mrs. George B. Adams, president and National Board member, Mrs. John Bauer, national recording secretary, Mrs. G. Carlton Potter, national director, Mrs. Carlton Wertz, Erie, Mrs. G. Scott Towne, Saratoga Springs, Mrs. Michael Schultz, Queens, Mrs. Wm. J. Lavalle, Queens, Mrs. Hirsch, Kings, Mrs. Otto Pfaff, Oneida, Mrs. Arthur J. Bedell, Albany, Mrs. L. H. Kice, Nassau, Mrs. H. F. Pohlman, Orange, Mrs. W. W. Street, Onondaga, Mrs. Alfred Madden, Albany, and Mrs. Earl of Oneida.

Most of us went on the sightseeing trip which included the airport. On the way back we were entertained at tea at the Lake Shore Hotel. That evening those of us who couldn't go for an air ride saw the New York State delegation, Mrs. Adams, Mrs. Bauer, and Mrs. Potter, looking very festive indeed, off to the dinner honoring the board of directors. It was held at the Union Club and Dr. Norman C. Yarian gave an illustrated talk on "Orchids."

On Tuesday work began in earnest and everything moved along smoothly as scheduled. The guest speaker was Miss Etta A. Creech who talked on "What Is Sound Health Education?" We were very proud to hear each of the standing committees mention New York State specifically as having done outstanding work. That made us just about 100 per cent in all departments. At the luncheon Dr. Van Etten mentioned the accomplishments of the Auxiliary in legislation in New York State.

The luncheon was held in the Rainbow Room of the Hotel Carter, honoring the past presidents of the National Auxiliary. Dr. Van Etten and Dr. Fishbein spoke to us. After luncheon there was a round-table discussion, "New Year," with Mrs. Charles H. Werner and Mrs. R. E. Mosiman, president-elect, presiding. National officers, state presidents, and state chairmen were invited to attend. For an hour there was an open discussion of auxiliary problems and how they have been handled in different sections of the country. I found it intensely interesting and stimulating.

Then we went on to the Cleveland Health Museum. I understand it is the only one of its

kind in the United States. Here exhibits are open to the public with the first floor devoted to Man's Heart, Man's Head, Man's Hands. The second floor has a room devoted to Mother and Child, another to fitness for defense, another to teeth. There are also special exhibits: Progress in Medicine, Periodic Health Examination, and Hands of Famous Surgeons. Then we were entertained at a lovely tea by wives of the trustees of the museum. That night we went to the open general meeting of the American Medical Association. There we witnessed the installation of Dr. Frank H. Lahey as president. In his address Dr. Lahey touched briefly on the precision of medical personnel, for the public deferment of medical students, selective act, medical education, elevation of medical standards, the nursing situation, anesthesia, and postgraduate education. Dr. Lahey stated his opinions clearly, there could be no doubt as to what his views were or why he held them. I liked his closing line, "a dangerous course has real advantages. It is the 'blood, sweat and tears' of the American Medical Association."

The Distinguished Service Medal was awarded this year to Dr. James Ewing, of New York City, for his outstanding work on cancer.

To go on Wednesday at 9 00 A.M. there was more session. This time the guest speaker was Dr. Helen A. Hunscher who spoke on "Nutrition Food for Fitness." She told us what went on at the government conference on nutrition called by the President. It looks as though we will all be "nutrition conscious" this year. To save time in making their reports the state presidents went up on the rostrum in a body, each carrying the flag of her state.

At the luncheon, held again in the Rainbow Room of the Carter, Dr. W. W. Bauer, Bureau of Health Education of the American Medical Association, spoke to us. The Advisory Council of the National Auxiliary was introduced, and then Dr. Lahey addressed us, followed by the Honorable Hatton W. Summers, chairman of the Judiciary Committee, House of Representatives, who blew off our bonnets with blasts against the attitude of the country today and the apathy of the people in general in relinquishing their democratic rights.

Afterward we went back to finish up the session of delegates. The slate presented by the nominating committee moved New York State's Mrs. John Bauer from recording secretary to first vice-president, president-elect, Mrs. Frank Haggard, Texas, second vice-president, Mrs. A. E. Anderson, California, third vice-president, Mrs. H. E. Christenbury, Tennessee, fourth vice-president, Mrs. P. R. Winston, Michigan, recording secretary, Mrs. Samuel Flowers, Kentucky, treasurer, Mrs. David Thomas, Pennsylvania, directors, one year, Mrs. Holcombe, West Virginia, Mrs. Oldenberg, Ohio, two years, Mrs. John B. Farley, Colorado, Mrs. James B. Simonds, Illinois, Mrs. W. K. West, Oklahoma. Following the election of officers, Mrs. Mosiman spoke, giving us the

NEW, INEXPENSIVE VACATIONS BY AIR

Physicians, arminded, should be keenly interested in offerings made by air transportation companies of vacations by air

One company, whose GTM comments that Americans are learning that air travel may be for pleasure as well as for business, has announced new inexpensive air cruises This is not only a new idea for vacations, but marks as well, a step forward in making air vacations really popular by bringing the rates within reach of more vacationers

These particular air cruises feature trips to our northern neighbor, Canada, and rates include transportation from New York and return, sightseeing in Canada, and hotel accommodations for a choice of vacations from five days to two weeks Other combination vacation land cruises to Florida include plane side trips to Cuba

Transportation by air is advantageous to the vacationer because the shorter traveling time permits longer periods of stay at the vacation resort

For those considering Canada as a vacation point this year, there is the additional incentive of having their money stretch further The American dollar is worth, at present, \$1 10 in Canadian currency Government officials of the Dominion are also appealing to the American tourist by pointing out that every tourist dollar is used for Canada's war efforts To publicize this, pins are distributed by the company conducting the air cruises, with crossed American and Canadian flags and the legend—"Vacation in Canada American money spent there fights for Democracy"

Information and reservations for the air cruises are easily obtainable at accredited Travel Agencies and Bureaus

One five-day cruise features a flight to Montreal with sightseeing to Mr Royal, Brother Andre's Shrine, Westmount Lookout and many other points of interest On the longer cruises of two weeks, Murray Bay and the Saguenay may be visited by steamer or additional time can be spent at the fine resorts in the Laurentians Ample time is permitted for shopping tours during the various cruises in either Montreal or Quebec

A second five-day air cruise provides sightseeing in Montreal for a day and a voyage down the St Lawrence to Quebec Accommodations are arranged for at the famous Chateau Frontenac, and side trips are made to Ste Anne de Beaufort, Montmorency Falls and through the quaint streets of Quebec so reminiscent of those in ancient towns of France

A six-day variation of the above cruise may also be taken In place of the steamer trip, this cruise features a motor tour between Montreal and Quebec

For vacationers with a full week to spend away from business cares, there is a trip that includes a steamer voyage to Quebec and Murray Bay, and up the Saguenay River For those who are able to stretch the time to a full week and two weekends, the steamer journey can be extended to a six day water cruise visiting in addition to Quebec, such quaint French-Canadian towns as Tadoussac and Bagotville

Another air cruise of from seven to fourteen days offers a choice of the river cruise to fashionable Murray Bay or a pleasant sojourn at the famous resorts in the Laurentian Mountains

A choice of any of these vacation suggestions would be a good selection and a Summer treat not soon forgotten

McKINNEY'S SANITARIUM

Under medical supervision tender and devoted care in an atmosphere unusually home like. Expert dietetic and nursing service Full cooperation with patient's personal physician.

highlights of her plans for the coming year. She touched briefly on each committee and we are fortunate in having a president with definite constructive work laid out. This meeting adjourned too late for us to take the trip to the Cleveland Cultural Center in Wade Park. But that night we did go to the reception honoring Mrs. Holcombe and Mrs. Mosiman. This was held at the Cleveland Academy of Medicine. A delightful musical program had been arranged for us and a talk by Kay Halle on the "Highlights of Cleveland"—historical, industrial, cultural, geographical. Then we were served a delicious wine punch and sandwiches and went upstairs to the Academy's medical museum. Thursday we had a bus trip through the lovely cultural gardens of Rockefeller Park, out through the exclusive Shaker Ridge residential section with its beautiful homes and on to the Country Club. There we had a delicious luncheon and grand fashion show in exquisite surroundings. The club is done in early American and reminds one of Williamshurg with its gorgeous crystal

chandeliers, hooked rugs, paneled rooms, etc. Thursday night, Mrs. Potter, Mrs. Towne, and I were the only ones left to go to the Auxiliary dinner and a reception and hall in honor of Dr. Lahey. But don't worry—we did you all proud. Then, Friday, I tried to fly home. I figured maybe the trouble with my not getting off the ground was that I kept trying for free flights. So-o-o with my last will and testament in one hand and my money in the other I called for a reservation. "All seats are taken on the 2-45 plane"—and that was the only one to Albany.

See you in Atlantic City.

MARY G. MADDEN

We are glad to welcome Warren County, and congratulations to Mrs. Leonard A. Hulseboach, the newly elected president.

Every good wish to each auxiliary for a pleasant summer vacation. May I hope to receive news from each county in September, and every month throughout the year.

OSLO PHYSICIANS REBEL AT "NEW ORDER"

An attempt by Major Vidkun Quisling's administration to introduce a "new order" into Oslo's lunatic asylum and what amounts to a kidnapping of its directors by the Hirden [Quisling Storm Troopers] have provoked a revolt by the entire body of Oslo physicians and medical personnel—about 2,000 in all—who threatened to stop work if political considerations received priority over purely professional qualifications, says a report from Stockholm to the *New York Times*.

Without the slightest reason the Quislingites decided to replace the chief sick warden of Dikemark, Oslo's lunatic asylum, directed by a psychiatrist of international repute, Dr. Roly Gjussing, by a member of the Nasjonalsamlag. Dr. Gjussing protested against this nomination, emphasizing that the nominee did not have sufficient professional qualifications, but his protest was to no avail.

Thereupon, all the chief doctors of community hospitals in Oslo drafted a protest to Major Quisling's administration in which they emphasized that the only criterion for the nomination of medical personnel must remain professional capacity. "If hospital personnel is dismissed for purely political reasons, the professional standards and efficiency of our hospitals will deteriorate, which in turn can have incalculable consequences for the health and even the life of our patients," the protest said.

Consequently, the chief doctors announced that they and all their colleagues, as well as the nurses and attendants, would resign if this practice was not abandoned.

On April 25 a group of the Hirden arrived at the Dikemark asylum and demanded to see Dr. Gjussing. When told he was examining a patient they went into his office and made him interrupt the treatment and drove him away to some unnamed place in Oslo.

On April 29 sixteen head doctors of Oslo hospitals gathered again in a special meeting and drafted a protest addressed to the Police Department, expressing indignation at the Dikemark incident and demanding the immediate release of Dr. Gjussing.

"Gjussing was arrested by individuals without police authority," read the protest, "and without even showing a warrant for his arrest. A public servant has been brutally interrupted in his work. He was removed from a more than usually responsible doctor's position without having the opportunity to take the necessary dispositions."

The relation between the patient and his doctor, which in all civilized countries is considered most sacred, has been violated. This is a revolting breach of the most elementary rights."

For the sake of the sick the doctors "demand guarantees for the protection of peaceful work, which is the foundation of all hospital work. If anything happens we decline all responsibility for the sick and we will be compelled to resign," the protest added. "This can be taken as the view of all doctors, assistant doctors, and medical candidates."

There has not yet been any answer to this or to the previous protest, and Dr. Gjussing is still in the Hirden's hands. At Oslo Police Headquarters a Swedish correspondent was told that the protest was being examined, and the responsible Hirden had been interrogated to discover the reasons for their action.

This conflict is considered throughout Norway as comparable in its gravity to the resignation of the Norwegian Superior Court of Justice and the famous protest letter from the Norwegian Bishop. The issue of it will decide whether one of the most sacred principles of civilization will be sacrificed by the totalitarian "new order."

Cobra Venom Solution H W & D

FOR three years, Cobra Venom Solution H W & D, has been used clinically for relief of intractable pain. During this period many thousands of doses have been administered with a measure of relief from pain reported in 50-70% of the cases treated.

Cobra Venom Solution H W & D, is a purified standard, sterile preparation supplied in ampules for intramuscular injection. It has been rendered clinically acceptable by removal in large measure of the objectionable hemotoxic and proteolytic constituents of crude venom the finished preparation being essentially a solution of cobra neurotoxin.

Indications. Reports indicate that Cobra Venom Solution H W & D, is particularly helpful in relieving severe pain associated with malignant disease. It has also been used to relieve pain in certain forms of arthritis, herpes zoster, Parkinson's disease and other neurologic disorders. In some cases the solution alone is effective; in others it is necessary to use it in conjunction with an analgesic. Dosage of morphine and other drugs may be reduced in a majority of patients.

The solution does not produce the objectionable reactions of morphine; is not habit forming; the margin of safety is wider; patients do not develop tolerance. Dosage is usually reduced rather than increased after relief has been established. No venous untoward reactions or changes in the blood of vital organs have been reported, but the solution should be used under careful medical supervision.

Supplied in boxes of ten 1 c.c. size ampules of solution containing 10 mouse units per c.c.

ELIXIR BROMAURATE

IS GIVING EXCELLENT RESULTS

IN WHOOPING COUGH

Shortens the duration of the cough, relieves the distressing spasms and gives the child rest and sleep. Also valuable in other PERSISTENT COUGHS and in BRONCHITIS and BRONCHIAL ASTHMA. In four-ounce original bottles. A teaspoonful every 3 to 4 hours.

GOLD PHARMACAL CO., New York

CLEAN HANDS AND CERTAINTY

Five days after the publication date of this issue of your JOURNAL is "St. Pontius Pilate Day." It is, if we are to believe the contents of an old almanac.

If you are not familiar with this special date on the calendar or its significance then you will want to know that St. Pontius Pilate is the patron saint of politicians, lawyers, lavatory attendants and of all good people who wash, wash, wash their hands.

A lot of water has splashed over the hands of the world since Pilate washed his of a bad decision, but clean hands have come to mean something more valuable to mankind than just an expression of clearing one's conscience. Humans have become a lot more careful about the handling of objects others are to dine on or convey to their mouths.

We have become so accustomed to seeing foods packaged that we almost give as little thought to the contents as we do to the packing. Perhaps we get too much of the impression that protection of a cover is surety of quality inside.

The same may hold true for drugs and dietary products used in the practice of medicine. Fancy and sealed

wrappings do not always contain the finest products. Of course, a manufacturer who takes pride in the perfection of his product will generally take an equal pride in the appearance of the package that conveys it. He even goes further and designs the package in a shape most practical and convenient for use as well as display.

On the other hand, the manufacturer less scrupulous will attempt to conceal poor quality with de-luxe trimmings that shout quality but do not back it up. To the layman, the beauty of the package may be a selling point and he or she may be influenced to some extent in purchasing a substitute and paying more for something actually worth less.

A physician, however, would know better especially pertaining to drugs and medicines. He has a choice of a number of reliable manufacturers for everything he uses—and generally makes a preference of one or two where all produce the same product.

How he obtains such preference may be a mystery even to himself—but he has acquired a good share of his opinions from watching and reading the advertisements that appear in this JOURNAL.

It is the physician's duty, when the occasion requires, to recommend a Funeral Director who is ethical—yet reasonable in price. You may have full confidence in our service.

REVIEWED

The Treatment of Diabetes Mellitus By Elliott P. Joslin, M.D., Howard F. Root, M.D., Priscilla White, M.D., and Alexander Marble, M.D. Seventh edition. Octavo of 783 pages, illustrated. Philadelphia, Lea & Febiger, 1940. Cloth, \$7.50.

This seventh edition carries forth the reputation built in previous issues. The work is rather encyclopedic in its scope. Dr. Marble's chapter on the physiology of diabetes and general considerations is well worth reading, not so much for new contributions but for its excellent outline of pertinent information gathered to date. His several hundred references are conveniently listed and add much to the value of the work. This favorable criticism carries throughout the book.

Dr. Howard F. Root's excellent section, "The Pathology and Causes of Death in Diabetes," is especially interesting because of the recently revived importance of pancreatic pathology in the concept of the disease. Throughout the book there are numerous references to the work of Best and of Lukens on diabetes of pituitary origin produced by parenteral administration of anterior pituitary extract.

Dr. Priscilla White has again covered the fields of diabetes in children and diabetes in pregnancy with her usual skill.

Dr. Joslin has rendered a real service to the medical world in the continued production of this important work.

GEORGE E. ANDERSON

The Extra-Ocular Muscles A Clinical Study of Normal and Abnormal Ocular Motility. By Luther C. Peter, M.D. Third edition. Octavo of 368 pages, illustrated. Philadelphia, Lea & Febiger, 1941. Cloth, \$4.50.

This book has been a standard American text on this troublesome subject ever since the first edition appeared 14 years ago. Much has been written and published on the eye muscles, but it remained for Dr. Peter to correlate it all and to add the results of his own extensive clinical experience. He has condensed it all into a meaty and wholesome text of some 360 pages which is complete without being padded, detailed without being dull, and presented in a style charming to read and easy to understand and remember.

The chapters on heterophoria and heterotropia are especially comprehensive and valuable, leaving the reader with a clear understanding of the subject. A new chapter on orthoptic training has been added to this edition which should be of immeasurable help in clarifying its use for those clinicians desiring to train technicians. There are many excellent illustrations and a complete index.

WALTER V. MOORE

A Laboratory Manual of Physiological Chemistry By D. Wright Wilson. Fourth edition. Octavo of 298 pages. Baltimore, Williams & Wilkins Company, 1941. Cloth, \$2.50.

This manual, which is intended for teaching purposes, is divided into two parts. Part I

deals with tests for inorganic constituents of biologic material, electrolytic dissociation, hydrogen-ion concentration, and colloids, also tests for alcohols, aldehydes, esters, carbohydrates, proteins, and fats. In Part II are given tests for body tissues and fluids, such as saliva, gastric and pancreatic juice, milk, blood, bone, muscle, bile, and urine. There are also metabolism and dietary deficiency tests. This manual should prove of value to the laboratory worker interested in physiologic chemistry as well as clinical chemistry.

E. H. NIDISH

The Therapy of the Neuroses and Psychoses. A Socio-Psycho-Biologic Analysis and Resynthesis By Samuel H. Krames, M.D. Octavo of 512 pages. Philadelphia, Lea & Febiger, 1941. Cloth, \$5.50.

The author regards psychiatry as dealing with the entire realm of abnormal human thinking, feeling, and acting in the social, physiologic, and biologic setting. He presents an adequate classification of the psychiatric states and the fundamental psychology of the psychoneuroses and psychoses. He pays considerable attention to the dynamics of symptoms, their meanings, and their interpretations.

He reviews the various schools dealing with the different subjects. Adequate evaluation of all types of therapy are presented, and the modern forms of shock therapy are evaluated. He has stressed those points of therapy which he has found most valuable. There are many case abstracts illustrating the different reaction patterns and forms of therapy.

It is a good book, both instructive and challenging. It is highly recommended. A bibliography to fundamental topics and subjects might enhance the value of this book.

IRVING J. SANDS

Principles of Abnormal Psychology. The Dynamics of Psychic Illness By A. H. Maslow, Ph.D., and Béla Mittelmann, M.D. Octavo of 638 pages. New York, Harper & Brothers, 1941. Cloth, \$3.50.

This excellent book on abnormal psychology, intended for the general practitioner and the college student, will prove a valuable addition to the few good books on this subject.

It does not adhere strictly to any one school of psychology but combines the desirable features of each. The elucidation of symptoms and their treatment is stressed throughout the book. The subject matter has been presented in a readable fashion, and the general practitioner will find it valuable in the treatment of many of the neurotic patients who come under his care.

There is an excellent glossary and a chapter on projective methods of examination which is helpful. The explanation of the symbols in the Rorschach test, the suggested readings at the end of each chapter, and the comprehensive bibliography will be found useful to those who seek further information on the subject.

Rehabilitation a Military Duty

"Registrants," said Brigadier General Hershey on May 23 of this year, "owe a duty to their government for service. That obligation calls for the service of a whole man—a man entirely alive—a healthy, strong, well-developed man. It is the duty of the registrant faced with this responsibility, to use every means available to make himself fit to serve."

In these words General Hershey states clearly and unequivocally the concept that every citizen has an obligation to perform his military duty and that no citizen should be permitted by reason of curable defect or infirmity to hide behind such defect or infirmity to avoid this obligation.

The question here raised is of the utmost gravity. No one will deny that the public interest, the public safety is paramount. No one will deny that especially in a time of unlimited national emergency the means to this end are justifiable. The government is requiring every qualified registrant to place his life in jeopardy in the interest of national defense. But what does government require of the physically disqualified? Of those men classified as 1-B? Or 4-F?

Medical Bulletin No. 5, June 30, 1941.* prepared by the Medical Division, New York City Selective Service Administration, under the direction of Samuel J. Kopetzky, Colonel, M. C., Medical Director, has this to say: "From a standpoint of rehabilitation, a considerable number

of men in 4-F will be found to have defects which medical therapy could correct and render them fit for full military duty. Furthermore, there will be found many classified in 1-B who are absolutely beyond the efforts of any medical care to render them fully competent for full military duty."

When the facts are fully known as to how many men in these classes can be rehabilitated by medical or surgical treatment, how many can be made available for "full military duty," what then? You have read above the attitude of Selective Service authorities as voiced by General Hershey that it is the "duty of the registrant faced with this responsibility, to use every means available to make himself fit to serve." And if the registrant does not see it that way, what then?

The *Bulletin* says: "an effort was made by this Headquarters to try a voluntary experiment in the area of one Local Board in Queens County where ancillary organizations were integrated to help the registrants rejected to quickly and easily secure medical service to relieve remediable deficiencies. This effort has been going on," says Colonel Kopetzky, "for two months, but I note no marked reaction accompanying this effort."

Physicians have contended from experience that many people would refuse medical care however readily and easily it was made available—even if it were put upon their very doorsteps. But, on

* Reprinted in full on page 1587

the other hand, many others interested sincerely in the betterment of the public health have thought otherwise and have said so

Now, apparently, further attempts are to be made to secure reliable evidence on this point, according to the *Bulletin*. "At each Local Board there will be one of these volunteer social workers who will make contact with the registrants classified in both 1-B and 4-F. A blank has been prepared which the registrant will fill out with the aid and assistance of the social worker. On this blank, among other things, the registrant will be asked

Will you accept remedial therapy

from your own private physicians? Give name of your private physician. If you are unable to employ a private physician will you use existing facilities in hospitals, voluntary or municipal, which have extended their facilities for this work to you, to have your defects corrected?

This procedure should yield statistics which will end all conjecture and controversy as to the facts. When these are definitely established, further consideration of rehabilitation, or prehabilitation, for registrants may properly follow a course to be determined when and after the facts are known.

Disease Is Our Business

We now live in a state of unlimited national emergency. Why? To many people, including some physicians unfortunately, these words "unlimited national emergency" are as the laughter of fools signifying nothing, being—as yet—unaccompanied by audible sound and fury. But to others they have a sinister meaning. They are a national dedication to a new way of life, not as formerly to peace and happiness but to war and destruction. They warn that the current of a great civilization has been abruptly reversed.

The frightful spectacle of European destruction which we have been observing from afar with foreboding has appeared, and to some still appears, to be only another war, war which has always been frightful, destructive, but which we have known before and shall see again in the days of our years. Many behold it with the eyes of Peter Ball¹ to whom

"A primrose by the river's brim

"A yellow primrose was to him,

"And it was nothing more."

But is this only war? This European thing? Look at it more carefully, physicians! You have trained eyes. Do you see nothing more than just another war? Or do you see something else? A

sickness perhaps, a deadly social malady of which the war is the festering ulcer? Do you suppose this sickness is responsible for the fact that, here in America, we now live in a state of unlimited national emergency? If so, what do you know about this sickness? Have you studied it? What do you know about it?

Medicine is not interested in war as war. It is the plaything of ambitious politicians. But disease, sickness, is our business. We should know about that. If war comes to us, Medicine can and will provide capable medical officers to the armed forces, it has done this before, it can do so again. Wars come and go. But what of the disorders beneath? What of the social maladies? What of these things, these diseases, which have produced "that bad man" with his ulcerous total war? Are you studying those diseases, physicians? Has Medicine sufficiently interested itself in these things? Has it studied them scientifically? Has it contributed to their relief and cure? Sickness is the business of Medicine. These social maladies have not fallen upon us like a sudden epidemic of influenza. They have been with us for a long time.

But because they did not break out with rashes or have vomiting spells or protruding eyeballs they were not recog-

¹ Peter Ball W. Wordsworth Part I Stan. 12

nized always, many did not and perhaps do not consider them to fall within the proper sphere of traditional medicine, but there they are, and they cannot be wished away. Some of these diseases were mere ideas in their inception not so long ago, little ideas which, in an environment of want, loose thinking, and neglect, flourished in those areas of cities long ago abandoned by the medical schools. Some of those dirty little ideas with running noses are now, with the passage of time, large ideologies. Are you studying them, physicians? You are no more immune from these social diseases than the rest of the population. They have grown, those diseases and the ideologies which were once little ideas, until they have crowded this Nation to the very brink of war as

the only remedy available, they have grown until they have reversed the whole current of our civilization, until "we have on our hands today a war without a definite prospect of peace" because "the enemy does not recognize peace as we know it, and we ourselves cannot define it."²

It appears to be imperative that Medicine should broaden its concept and study to include those diseases of society, those social disorders among which it must live and move and have its being. To neglect this study is to invite oblivion, or

"Is it nothing to you, all ye that pass by?"³

² Fortune 24 No. 1, 34.
³ Lamentations I. 12.

Eternal Vigilance

It is a fixed policy of the Medical Society of the State of New York to safeguard the modes of medical practice which have secured to the communities of the state its present high level of health. These modes of practice, providing preventive, curative, and public health measures, have been the outcome of a slow but reliable method of trial and error by which the proved good has been retained and the unworkable or undesirable has been thrown out.

Now it is inevitable and inescapable that under the banner of National Defense, and because of the pressure of lack of time for full debate and inquiry, many propositions will arise from diverse quarters—proposals to inaugurate new medical services or to expand existing ones in the service of the communities. Some of these proposals may be good, others bad, only time and experience can decide.

The 1941 meeting of the House of Delegates declared "It is the expressed policy of the Medical Society of the State of New York that, at their introduction, the temporary nature of necessary health measures be stressed as they are developed

and that no general program shall be approved coming under the terms of 'part of the Defense program' which would permanently change the nature and mode of the present method of medical practice."

This is, in effect, a mandate to the legislative committee to exercise in the future more than its usual vigilance in scrutinizing and analyzing all Federal and state bills which might constitute part of the Defense Program and to appraise their medical significance. The tendency among legislators is to enact such legislation loosely as is asked for by the administration without writing in any limitation as to time of expiration.

A noteworthy example is the Reconstruction Finance Corporation. It was created by Congress to make distress loans to agriculture, business, and banking under the Hoover administration—and for the duration of the emergency only. Simply that and nothing more. It is still going. Of itself and through its creatures it is interested in nearly every kind of business there is. Senator Adams said of it "that under the bill the RFC

could enlist and drill an Army if they assert it is in the interest of national defense "

We cannot urge too strongly that the mass of coming legislation be carefully

combed by the legislative committee for amendments and riders which often constitute the rent in the fabric through which the camel eventually enters the tent

District Branch Meetings

Arrangements have now been completed for the annual meetings of the District Branches

Date	Branch	Where Held
Sept 18	Sixth	Bassett Memorial Hospital, Cooperstown
Sept 23	Fifth	Syracuse
Sept 25	Seventh	Oak Hill Country Club, Rochester
Sept 26, 27	Fourth	Lake Placid Club, Lake Placid
Sept 30	Third	Catskill
Oct 2	Eighth	Jamestown
Oct. 8	First	Mt Sinai Hospital, New York City
Nov 12	Second	Garden City Hotel, Garden City, Long Island

In these rapidly moving times it behooves the membership of the State Society to attend these meetings and to profit by the programs which this year will be of exceptional interest and timeliness

We therefore publish at this time the schedule of these meetings in order that you may note the dates and locations. You may not say that you have not been notified well in advance. Of course, you may not read your JOURNAL—that can happen to anyone—but the Editors hope that few will fall into this category. It is to be hoped that the attendance at these meetings will break preceding records. Make a note now, delay is fatal.

Special Article

Military Medicine in New York State Army Posts and Camps

Foreword

MUCH has been published about men disqualified under the Selective Service Act for full military duty. Little, however, has been said about the men who have been accepted. What are they doing? How and where are they being cared for medically? What problems have been created by the new camps and the rapid expansion of old military posts in the State of New York?

Because it was felt that this information would interest readers of the JOURNAL, the editors set out to discover what they could. Through the courtesy of the military authorities of the Second Corps Area, visits were made to Plattsburg Barracks, Fort Ontario, Madison Barracks, and Pine Camp, where they were received with every courtesy and where every facility was placed at their disposal to visit

the hospitals. The following is an account of what they observed.

General Conditions

At the posts and camps visited the hospitals are adequate in size and well equipped with the most recent mechanical, electrical, and other professional apparatus. Drugs and other expendable supplies are well stocked. Buildings, even where old, are scrupulously clean and evidence of recent painting is seen everywhere. In some, designed for smaller personnel, mess halls have been found inadequate, but new construction or rearrangement of rooms for this purpose is being carried out.

The hospitals are being conducted with well-organized services in medicine and surgery and with most of the special services, such as eye, ear, nose and throat, urology, x-ray, psychiatry, etc., represented. The staffs are

in most cases up to full complement. Everywhere we observed a great alertness and enthusiasm for their work on the part of the personnel, both officer and enlisted. It must be considered that most of the officer personnel have been on their present assignments less than a year and, more often, less than six months. It is a tribute to the profession and to the high quality of their training that, considering the short length of time they have worked together, the morale, teamwork, and the overall efficiency of the staffs are at once noted by the observer.

In camps and posts the function of the hospital is to provide medical service for (1) the permanent garrison, (2) the National Guard units (now federalized), which are stationed there for training, (3) the inductees as they become assigned to these units, (4) the CCC men operating within the area served by the camp or post, and (5) such R.O.T.C. units as may be assigned there for training in the summer.

No civilians are accepted for treatment except (1) those who are permanently employed at the post or camp as civilian employees or (2) accident and emergency cases occurring on or adjacent to the post. First aid is rendered when required, and the case is then referred to a civilian physician or nearby hospital.

At least eight hours of active duty are required except for the medical officer of the day, who is on duty for the full twenty-four. His duties combine both medical and administrative detail. Each regiment stationed in the area has and operates its own infirmary with its own medical officers and enlisted personnel, where sick call is held and cases are disposed of either by admission to the hospital or return to "quarters" or "duty." There is no status of "light duty." The Army's policy is that a soldier is either fit for duty or should be hospitalized, the carrying of patients "in quarters" is discouraged.

Chief nurses have the relative rank of first lieutenant and ward nurses the relative rank of second lieutenant. Their duties are similar to those of nurses in similar capacity in civil hospitals. Ward attendants do many of the arduous duties ordinarily required of ward nurses in such hospitals.

Your editors ate at the officers' mess, the food was sufficient in quantity and of good quality. They visited hospital kitchens, the enlisted men's food was good and substantial. In most places special diet kitchens were either in preparation or actually functioning where needed.

Who Is Treated for What?

It is important to visualize what is going on in this training period in order properly to evaluate the function of the Army station hospital. Into these posts and camps, expanded by the addition of new barracks, streets, and sanitary facilities, have come all kinds of units—infantry, artillery, coast guard (anti-aircraft)—in all stages of mechanization with their light and heavy tanks, their new reconnaissance cars, light and heavy trucks, motorcycles, etc. The trainees first have thirteen weeks of basic training and then commence specialized training. Thus, in addition to the ordinary expectancy of infectious diseases—infections of the upper part of the respiratory tract, measles, mumps, and scarlet fever—must be added the possibility of casualties and other injuries. Men in the camps and posts visited come from New York State principally, but some are from the Middle West. Nearly all of the officer personnel of the hospitals is derived from New York and New Jersey.

Acute surgical cases are usually handled at the post or camp hospital. Elective surgery, fractures of long bones and vertebrae, and cases that require more than sixty days of hospitalization ordinarily are transferred to a general hospital. In spite of this, plenty of work exists, and medical officers stationed at these posts and camps should not lose their technical skill and training. It must, of course, be realized that the vast bulk of the patients come from a rigorously selected and carefully hardened group of young men, with the exception of an occasional civilian employee who is injured on reservation and cannot be moved to a civilian hospital and also a few veterans occupied on CCC projects. This necessarily limits to a certain extent the variety of medical and surgical conditions to be encountered on the one hand, while the nature of the training and the increasing mechanization of the Army are creating some new and interesting problems.

Problems in Sanitation and Public Relations

The influx into various communities of large numbers of young men is bound to create a number of problems. The Army pays once a month, and the purchasing power of the men rises to a sharp peak. This is conducive to a concentrated form of recreation, although it is controlled by judicious use of the pass privilege. In the towns and villages adjacent to the camps and posts that we observed, the

utmost order was maintained by the local authorities operating in conjunction with the military police

The recreation problem outside the camps is now being taken over by the United Service Organization. While not strictly a concern of military medicine, it does have a bearing upon physical and mental health. Opportunity for recreational activities exists in local moving-picture houses, the Y M C A, and various athletic sports.

Venereal disease seems to be well under control due to the excellent cooperation between the civil and military authorities. Prophylactic stations are always accessible. The opinion was expressed that venereal disease in the Army

is on the decrease. This appears to be partly due to the educational campaigns carried on by various interested organizations. It must also be said in fairness that the inductees represent an intelligent group of men. Public health education has made great strides since the last war, the Boy Scout movement has developed, and common sense in public education has been progressive, and apparently effective, with respect to the general average of literacy. The radio, too, must be credited with its share in promoting health education. All of these considerations have weight, together with the campaign ceaselessly waged by the Medical Corps, in reducing the incidence of venereal disease in the posts and camps.

HEADQUARTERS SECOND CORPS AREA
OFFICE OF THE SURGEON
GOVERNORS ISLAND, N Y

July 10, 1941

To the Editor

According to information received from the Surgeon, Seventh Corps Area, the Director of the Mayo Foundation has announced that the Medicomilitary Inactive Status Training Session of the Mayo Foundation, scheduled for October 5 to October 19, 1941, will be suspended during the present emergency. Notice through

Corps Areas and Naval Districts will be published upon resumption of the school.

This announcement is submitted for the information of the members of the Medical Society of the State of New York.

Very truly yours,

C M WALSON,

Colonel, Medical Corps, Surgeon

ERRATA

IN THE article on Medical Libraries in the State of New York, published in the JOURNAL on May 15, two libraries were confused: the Library of the Division of Laboratories and Research of the New York State Department of Health in Albany, and the National Health Library in New York City.

The National Health Library in New York City is supported primarily by member agencies of the National Health Council, which coordinates the work of seventeen national voluntary health associations. The library collection emphasizes public health and preventive medicine rather than purely medical subjects. An index to current periodical literature in the field of public health is issued weekly for a small annual subscription. Members of the organizations supporting the library, and others paying a nominal fee, are entitled to the privileges of the library. The library receives, by exchange or gift, about 500 magazines and the annual users number about 1,000.

The Library of the Division of Laboratories and Research of the New York State Department of Health in Albany is maintained for the staff of the central laboratory in Albany and the Branch laboratory in the City of New York, in addition, consultation services are available to 127 laboratories of the state that are approved for bacteriologic and pathologic examinations. The library is primarily for reference and research, no materials are lent outside the laboratory. In addition to the services in preparation of bibliographies, abstracts, and translations, a current literature index is maintained on subjects of particular interest to the Division. In the Albany library are 5,800 volumes and in the Branch there are 1,334. The library receives annually 45 foreign and 68 domestic journals, and the Branch, 23 domestic and 10 foreign.

The editorial and publications section, as well as the museum of the laboratory, is in the library department. The collection of 2,000 tissue slides, mainly oncological, is available for loan to pathologists in the approved laboratories of the state and to qualified candidates.

RECENT DEVELOPMENTS IN BACTERIOPHAGE THERAPY

WARD J. MACNEAL, M D, New York City

AT THE New York meeting in 1938, I presented before the Section of Pathology and Clinical Pathology¹ a discussion of the therapeutic use of bacteriophages, particularly in sepsis. The statements made then in regard to the nature of bacteriophages and the mechanism of their action require no revision at this time. It is most satisfactory to regard them as minute, particulate living structures of extremely limited biologic adaptability, similar in general to the many other members of the group of filterable viruses. Like other living things they evidently carry on many of their vital activities through the agency of enzymes, which may, in some instances, be separated from the living particles that produce them. The effects of bacteriophages in therapy depend to some extent upon their invasion of the infecting bacteria to cause an alteration of them similar to the lysis seen in the test tube. Such effects may be observed within the urinary bladder and doubtless occur also in the intestinal lumen. However, in pus and in blood this mechanism of lysis is partially or entirely inhibited. Here the bacteriophage seems rather to alter the bacteria so that the latter become more readily subject to phagocytosis, and the bacterial destruction is then accomplished by the phagocytic cells, aided to some extent in their digestion of the bacteria by the associated bacteriophages.

Experience in clinical use of bacteriophages has been gradually accumulated. The attention and effort required for administration of these agents are such that their extensive exploitation is not likely to be sudden and rapid, and for the same reason the disease conditions are often permitted to reach the extreme stage before the bacteriophage treatment is employed.

It is still necessary to emphasize that bacteriophage therapy is directed against a specific infectious agent and is not to be regarded as a panacea for treatment of inflammation of unknown causation. The most common infections in which these agents are effective are those diseases due to the staphylococci and the colon bacilli, but there are many other infections in which they are helpful.

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, April 29, 1941.

From the Department of Bacteriology, New York Post-Graduate Medical School and Hospital, Columbia University.

Intravenous administration of the bacteriophages is the method of choice. For this purpose the bacteriophage preparation² should be as free as possible from other substances that might exert a deleterious effect or cause a reaction. We have, therefore, used a culture medium in which the amino acid, asparagine, is the sole source of nitrogen, made with pyrogen-free distilled water with utmost care to exclude undesirable substances. The preparation of bacteriophages is a specialized field of bacteriologic laboratory work, and those who prepare these agents for intravenous use should devote special study to the matter. Fortunately, there is no actual difficulty in obtaining the proper bacteriophages from the laboratories offering special service in this field if the physician is able to make a specific diagnosis and to supply a culture of the infecting microbe to such a laboratory for identification and bacteriophage testing.

In 1938 there was demonstrated to this Section a patient who had recently recovered from staphylococemia with a localization in the tibia. This boy has remained entirely well during the intervening three years. He has been seen from time to time and has received an occasional intravenous dose of phage as insurance against relapse. Our experience in the bacteriophage therapy of osteomyelitis has become quite extensive. It is evident that this agent aids in saving lives in the acute stage of hematogenous infection, in preserving the integrity of limbs free from scars and chronic sinuses, in promoting more rapid healing even after incisions have been made, and in suppressing the threat of renewed activity in latent foci of the infection weeks, months, and years after the primary disease.

Case Reports

E. W. P., one of our patients successfully treated for staphylococemia in 1930,³ developed excruciating pain in his right tibia in May, 1938. A roentgenogram (Fig. 1) revealed a small abscess in the cortex of the tibia. The patient, himself a surgeon, elected to receive intravenous bacteriophage rather than incision and drainage. Starting with an intravenous dose of 2 cc of staphylococcus bacteriophage, he received daily injections in increasing amounts up to 5 cc. The severe pain was relieved within two days, and the patient was walking in three weeks and playing tennis at the end of six weeks. There was no

FIG 1 Roentgenograms of the right leg of E W P on May 10, 1938, with small abscess in the mid portion of the tibia after a latent period of eight years subsequent to staphylococcemia in 1930. Prompt recovery followed intravenous bacteriophage therapy without incision. The normal left leg is shown at the right of the two views of the right leg.

FIG 2 Roentgenogram of the left hip of A M on March 22, 1939, showing a small abscess in the femoral head at the epiphyseal line, subsequent to staphylococcemia in 1934. The treatment by rest in bed, moderate traction and vigorous intravenous use of staphylococcus bacteriophage was followed by complete restoration to normal function.

incision and there has been no further recurrence of the disease.

A. M., a boy born June 23, 1924, who had survived a staphylococcemia treated with bacteriophage in 1934, developed pain and swelling within the joint capsule of the left hip about February 1, 1939. A roentgenogram (Fig 2) revealed a lesion in the epiphyseal line at the femoral neck within the joint capsule. Rest in bed with moderate traction and vigorous intravenous use of staphylococcus bacteriophage from March 27 to July 1 was followed by complete restoration to normal without incision. The patient walks without a sign of a limp. He is still under observation and has recurrent activity of his disease in other locations from time to time, usually not serious enough to confine him to the house.

We⁴ have recently assembled for publication a series of 500 cases of staphylococcemia accessioned to our bacteriophage files in the ten years of 1931 to 1940. The recovery rate was 34 per cent. In this large group there were numerous examples of localizations of the infection of special interest. There were more than 50 of these in which there was obstruction of venous flow through the cavernous sinuses, a condition commonly diagnosed clinically as cavernous sinus thrombosis. In addition, there were several other patients with clinical evidence of obstruction of the cavernous sinus and staphylococcal infection of the face for whom convincing positive blood cultures were lacking. Hence, these patients were excluded from the staphylococcemia series but may quite properly be included in the group of septic staphylococcal obstruction of the cavernous sinuses. In this group of approximately 60 patients there have been 16 survivals, 13 of them with blood cultures positive for *Staphylococcus aureus* and 3 without positive blood culture. Cavernous sinus thrombosis associated with staphylococcal infection is a highly fatal disease. These recoveries are therefore of peculiar interest. A few of them will be briefly described.

Case Reports

A. P. was admitted to Morrisania City Hospital on September 7, 1934, with temperature 104 F and pain and swelling about the left eye of five days' duration. There had been a furuncle on the tip of the nose about August 17. On admission there was proptosis of the left eye, with edema of lids and of bulbar conjunctiva, partial aphasia, and signs of early pneumonia. Thrombosis of the angular vein was followed by generalized invasion of the blood stream, periorbital abscess, extensive osteomyelitis of the frontal bone, abscess of the temporosphenoidal lobe of

Fig 3a

Fig 3b

Figs 3(a) and 3(b) Abbreviated clinical record of M C, girl, aged 8, with furuncle on cheek, clinical signs of septic obstruction of the cavernous sinuses and five blood cultures positive for *Staphylococcus aureus*. A series of intravenous injections of staphylococcus bacteriophage to a total of 19 cc on September 3 was followed by a Hugh Young reaction, and with continuation of the bacteriophage therapy the patient recovered. After discharge from the hospital she developed a metastatic lesion in the right hip which required renewal of the treatment for a long period but eventually healed

the cerebrum, and complete recovery following a series of surgical procedures aided by the use of bacteriophage locally and intravenously. This case has been reported by Smith,⁶ the attending surgeon who has recognized that a hopeless situation was here transformed by use of the bacteriophage.

M C, a girl aged 8, was admitted to the hospital on August 28, 1933, with a diagnosis of erysipelas of the face, forehead, and scalp. There was a furuncle on her cheek. Large doses of erysipelas antitoxin were given on August 28 and 29, without effect. A blood culture taken on August 29 yielded a heavy growth of *Staph aureus*, first reported on August 31. Subsequent blood cultures taken on August 31 and September 2, 4, and 6 were all positive. On August 30 there was marked edema of the right eye, and on the next day this had extended to the left eye. On September 2 incisions were made in the scalp, forehead, and nose. Exudate from all these sites yielded growth of *Staph aureus*. At a consultation on this day enucleation of the right eye was discussed, but this action was deferred. On September 3 staphylococcus bacteriophage was given in a series of intravenous injections to a total of 19 cc, followed by a shock reaction and a temperature rise to 105.8 F, and prompt fall to 102 F. The phage injections were continued, morning and evening, and on September 6 another series of doses to a total of 23.5 cc was followed by chill and temperature rise to 104 F. The smaller injections of phage were then continued until September 27. The patient was discharged in good condition on October 7. However, as so often happens when bacteriophage therapy is discontinued too soon, there was a recurrence of active infection in the form of metastatic osteomyelitis and arthritis of the right hip, for which she was admitted to another hospital on October 24, 1933. The swollen hip opened spontaneously, and from it a culture of staphylococcus

Fig 4b

Figs. 4(a) and 4(b) Abbreviated clinical record of E C, woman, aged 55, with lacerated furuncle of the right cheek. A blood culture taken September 7 gave positive growth of *Staphylococcus albus* and a clinical diagnosis of thrombosis of the cavernous sinus was made on September 8. The transfusion on September 7 was followed by a sharp reaction. Staphylococcus bacteriophage was injected intravenously in series to a total of 94 cc during the night of September 8 and further injections were given on September 9 and 10. There was prompt improvement and eventual recovery

Fig 5h

FIGS 5(a), 5(b), 5(c), 5(d), 5(e), 5(f), 5(g), and 5(h) Abbreviated clinical record of H. D., boy, aged 19. While convalescing from meningococcus meningitis, this boy developed a staphylococcal infection of the meninges, first recognized as such on November 25. After vigorous use of staphylococcus bacteriophage by injection intravenously into the spinal canal and into the cisterna magna, the patient made a complete recovery and has remained free from reactivity of the infection.

was obtained. Blood cultures remained negative. Local and intravenous bacteriophage therapy was again instituted. She was discharged from the hospital on March 1, 1934, and reported in perfect condition on April 25, 1934, and again on June 4, 1934.

In this patient the evidence of infection of the blood stream is convincing, and the clinical signs of obstruction of the cavernous sinuses are quite definite. The postmortem evidence of thrombosis is lacking. The abbreviated clinical record is shown in Fig 3.

E. C., a woman aged 55, observed a small furuncle on her right cheek about August 23, 1939. Wet dressings were applied. On August 31 her physician prescribed sulfanilamide and local hot compresses. She accidentally fell on September 1 and suffered lacerations of her forehead and left infraorbital region. She was admitted to the hospital in the evening with temperature 100.6 F. There was an indurated area extending from the bridge of the nose 5 cm. to the right, and in this there was a small incision. The sulfanilamide was continued, 120 grains daily on September 2 and 3 and 30 grains daily on September 4, 5, and 6. Then sulfapyridine, 90 grains per day, was given on September 7, 8, and 9. At 5 00 P.M. on September 7, a blood culture was taken and a transfusion of 460 cc given. There was a rather sharp reaction following the transfusion, and on the next day the blood culture had developed a growth of staphylococcus, subsequently identified as *Staph. albus*, completely susceptible to bacteriophage. On September 8 a diagnosis of cavernous sinus thrombosis was made. Bacteriophage was given in a series of intravenous doses from 6 30 P.M. September 8 to 7 30 A.M. September 9, to a total of 98 cc., without reaction. Further intravenous injections were given, 14 cc. at 11 30 A.M., 20 cc. at 4 00 P.M., 25 cc. at 8 00 P.M., 25 cc. at midnight, 25 cc. at 9 00 A.M. September 10, and 25 cc. at 4 30 P.M. on this day. Her abbreviated clinical record is shown in Fig 4. In view of the course of the disease after bacteriophage was started and the eventual recovery, the diagnosis of cavernous sinus thrombosis may be thought to have been premature but, nevertheless, fortunate. We are not informed concerning the detailed observations leading to this diagnosis.

Generalized leptomeningitis due to staphylococci is another disease of high mortality, so that any recovery may be considered remarkable. There are several of these in our series. Space will permit the presentation of only 1 case.

Case Report

H. D., a boy aged 19, was treated by Dr O'Connor and Dr Connolly at St. Elizabeth's Hospital, New York City, with Dr Josephine Neal in consultation. We are indebted to these physicians for the clinical record, which is shown

in abbreviated form in Fig 5. The boy suffered from a meningococcal meningitis, which responded to treatment with meningococcus serum. There was a serum shock on October 29 following an intravenous injection of 10,000 units of the serum. About November 17, when the patient seemed well on the road to recovery, there was a renewal of fever, and on November 18 reactivation of the inflammation of the meninges was distinctly evident. This relapse was recognized as due to a secondary infection with staphylococcus on November 25, and upon recommendation of Dr Neal the staphylococcus bacteriophage was administered, 5 cc into the spinal canal and 73 cc intravenously in a series of injections from 7 00 P.M. November 25 to 10 30 A.M. November 26. Spinal block soon developed to interfere with the intraspinal therapy, but this complication was met by employing cisternal puncture as indicated in the chart. Subcutaneous injections of toxoid were also given on December 13, 15, 17, and 21. The patient made a complete recovery and was discharged on January 18, 1937. He has reported from time to time and has remained free from recurrence. The favorable result may reasonably be credited in part to the bacteriophage but in a large measure also to the diligence, clinical wisdom, and skill with which it was employed in a difficult situation.

Summary

1. Bacteriophages are filterable agents belonging in the virus group, capable of attacking, altering, or destroying particular bacterial species under certain conditions.

2. In the interior of the body their action is somewhat limited and in staphylococcal infections appears to result chiefly in rendering the bacteria more readily susceptible to phagocytosis and intracellular digestion.

3. Bacteriophages for intravenous use require special care in their preparation, and their administration to the patient also requires knowledge, skill, and diligence.

4. By the skillful use of bacteriophages, low-grade infections often are rendered trivial, acute infections may be aborted, deep-seated lesions may heal without drainage, and desperate conditions may be caused to heal in a surprising manner.

5. Continued use of staphylococcus bacteriophage tends to forestall and prevent relapse after staphylococcemia and other staphylococcal infections.

Discussion

Dr Joseph Felsen, *New York City*—I have followed Dr MacNeal's work on the therapeutic application of bacteriophage with considerable interest for many years. The brilliant results reported by Dr MacNeal in cases of bacteremia are not paralleled, however, in bacillary dysentery. Following d'Herelle's original report, a number of investigators administered bacteriophage to patients with acute bacillary dysentery under carefully controlled conditions. The majority were unable to substantiate the usefulness of bacteriophage in this disease. Our experience in the Jersey City epidemic of atypical Flexner dysentery in 1934 in a limited number of cases, including controls, was quite similar. Indeed, the control cases appeared to recover somewhat sooner than the bacteriophage treated cases. It is quite possible that differences in therapeutic efficiency may be due to variations in potency rather than to strain specificity. Generally speaking, most dysentery bacteriophages are group-specific rather than type-specific. In this connection we have found bacteriophage useful as a confirmatory diagnostic laboratory procedure in cases of acute and chronic bacillary dysentery in which the specific dysentery organism could not be recovered. Feemster is a firm advocate of this procedure, and we have often found it helpful in chronic distal ileitis and chronic ulcerative colitis following an initial attack of acute bacillary dysentery.

Dr Ward J MacNeal, *New York City (concluding remarks)*—Bacteriophage active against pneumococcus has been reported in the literature, but we have not had a potent pneumococcus phage in our possession. Various bacteria may undergo autolysis or may be readily dissolved in certain mediums. The solution of the meningococcus and of the gonococcus is apparently due to enzymes that are essential constituents of these bacteria. Undoubtedly, there are many agents that take part in the solution of bacteria.

Stock bacteriophage is kept ready for immediate use. The specific bacteriophage can be prepared only after the culture of the microbe from the particular patient has been made available for its preparation. On that account we

request that such culture be sent to us at the earliest possible moment. We send out the stock phage and proceed without delay in the attempt to prepare a specific phage. This work may require several days. As soon as it is ready the specific phage is substituted for the stock phage previously employed.

For many years we have used chemotherapeutic agents in conjunction with the bacteriophages, and in the report before the Section on Pathology and Clinical Pathology in 1938 we mentioned the use of neocarsphenamine. Of the sulfonamides, the sulfathiazole and sulfapyridine appear to exert an effect upon staphylococci. We have used them in conjunction with the bacteriophage. Sulfathiazole appears to be extremely helpful in control of the earlier stages of severe staphylococcemia, but we have found it less useful in treating metastatic localizations. Therefore, we recommend using sulfathiazole and bacteriophage for the first two weeks, then we discontinue the sulfathiazole and continue the phage, even for many months after apparent recovery.

Hemolytic streptococci are usually resistant to the bacteriophages in our collection. In about 1 case out of 20 we succeed in obtaining a potent phage for organisms of this type, and in such cases the phage has seemed to be of help. Of course, infections with the hemolytic streptococci usually respond to the proper use of sulfanilamide.

Dysentery phages have been used with success by D'Herelle and his associates, particularly in the more malignant types of Shiga dysentery. Our own experience has been limited. In our series there have been no deaths.

Untoward reactions to bacteriophage therapy are lacking. The therapeutic shock, which we have designated as the Hugh Young reaction and which is intentionally induced at the proper time, consists of chill, temperature rise, diaphoresis, temperature fall, and immediate improvement. The chill and the fever may be frightful to the uninitiated. The therapeutic use of bacteriophage requires skill and attention.

The expense should not be a bar to the use of bacteriophage. Telegraph, telephone, air mail, and air express services cost money. The charge for the bacteriophage itself is adjusted in our laboratory in accordance with the recommendation of the attending physician who requests it.

HITLER'S MEDICAL RECORD

To the Editor of the *New York Times*

John Cudahy, in today's description of his interview at Berchtesgaden, unwittingly gives renewed currency to the falsehood that Hitler was blinded by gas in the last war. This statement has been merely part of the stage build-up of the Leader.

In 1935 I was told by one of the greatest medical men in the Reich that in 1932 he had himself

investigated Hitler's official medical war record. It consisted of one hospital admission. Diagnosis "hysterical amblyopia," i.e., blindness due to a hysterical fear-reaction. In 1934 my friend found this record no longer existed.

PREPARATION OF DESICCATED HUMAN PLASMA BY MASS PRODUCTION METHODS

Its Importance in Routine and Military Surgery

J M HILL, M D , Dallas, Texas

DURING the past twenty months the desiccated plasma service of Baylor University Hospital has made concentrated plasma available in any needed quantity and at all times in the same manner as other intravenous fluids. Since its inception as the first routine hospital service of its kind, 660,000 cc of blood have been drawn, the plasma separated and desiccated from the frozen state by the adevac process, and the redissolved plasma administered in concentrated form to over 250 patients in Baylor University Hospital and to an undetermined number of patients outside the hospital.

The advantages of plasma as a blood substitute and even as a therapeutic agent superior to blood in some conditions have been adequately stressed in reports by Levinson and associates,¹ Scudder,² Struma, Wagner, and Monaghan,³ Elliott, Tatum, and Nessel,⁴ and others. However, serious disadvantages have hampered the use of whole plasma. Contamination has proved to be a problem because liquid plasma is an excellent culture medium. Drew and others⁵ have described the finding of staphylococci, as well as nonpathogens, in stored liquid plasma. Even at relatively low temperatures there may be proliferation of the nonpathogenic soil bacteria, the so-called pyrogens whose proteins are responsible for many of the severe febrile reactions to intravenous fluids. To make things worse, the slow precipitation of fibrin which occurs in all liquid plasma closely simulates bacterial growth and hampers use.

By contrast, properly dried plasma has many advantages that establish its definite superiority for civilian and military use. These advantages may be divided into those directly due to the desiccated state and those due to the concentration that the dry product makes possible. Desiccated plasma has the following advantages:

A Perfect storage characteristics

- 1 Can be kept anywhere for instant availability

- 2 Indefinite preservation of biologic properties
- 3 Does not permit bacterial growth
- 4 No precipitation of fibrin
- 5 No discoloration
- 6 No refrigeration required. Dryness protects from high temperatures

B Reduction in bulk.

C Great reduction in weight

D "Flash" solubility if dried from the frozen state

E Large reserve stores can safely be built up and kept indefinitely for civilian and military emergencies

F Economy—no waste through bacterial growth or other deterioration, reduced cost of transportation and nonrefrigerated storage

The following benefits are obtained when the desiccated plasma is used in the hypertonic or concentrated form:

A Increased therapeutic potency

- 1 Prolonged and powerful hypertonic effects—reduction of increased intracranial pressure, withdrawal of edema fluids, etc
- 2 Stimulation of vascular system in shock.
- 3 Most rapid increase of blood volume in shock.
- 4 Rapid correction of severe hypoproteinemia

B Simplicity and speed of administration with glass syringe. No tubing or complicated apparatus

C Instant availability—can be carried and kept anywhere

Source of Blood

The Baylor Hospital Blood Bank serves as the source of blood. In fact, the bank was actually established largely for this purpose following the successful solution of the problem of volume desiccation. Initially, a considerable amount of plasma was obtained from blood outdated at the tenth day of storage. However, as our volume turnover increased, this source decreased until at present no blood is permitted to become more than four days old before it is used by the plasma service.

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, Buffalo, April 30, 1941.

From the William Buchanan Blood, Plasma and Serum Center, Baylor University College of Medicine.

Another factor in this connection has been the fact that practically everyone pays back blood borrowed from the bank rather than make a deposit in anticipation of a transfusion. Although we have had no bad results from the use of blood up to fourteen days old or from plasma derived from such blood, we agree with Strumia, *et al.*,⁶ that a five-day maximum for storage is desirable in order to minimize the possibility of proliferation of the occasional and inevitable slight contamination of bacteria derived from the skin at the time of venipuncture.

Methods

The blood is drawn and stored in a completely closed system employing a vacuum-sealed bottle containing sodium citrate solution. The venipuncture set has been simplified and consists of a length of good quality tubing with an observation tube and needle at each end. The tube is clamped with a hemostat to hold the vacuum, one needle is plunged through the sterile rubber diaphragm and the other is introduced into the vein. The vacuum is then allowed to draw blood into the bottle, which is given a rotary shaking movement by means of a specially designed motor-driven rotary shaker. With three such bleeding stations we have bled 122 donors in eight hours and separated the plasma the same night under the pressure of an emergency.

Second only in importance to the method of desiccation is the use of the continuous separator of the DeLaval type. This method has long been in use for the preparation of veterinary serums. Although Bushby, Buttle, and Whitby⁷ in England have reported the successful separation of human serum, its use for this purpose has not been reported heretofore in this country.

Twice a week the blood for plasma is removed from the bank, and while it is still cold the blood is pooled in a large stainless metal reservoir and immediately passed through two DeLaval serum separators. The first unit separates the red cells, the plasma passing to the second unit, which acts as a clarifier removing fat droplets and residual red cell fragments. We have slightly modified the bowl covers and spouts to make a practically closed system. This whole process should, of course, be performed in a dust-free room. Nevertheless, with reasonable care, such as keeping doors and windows closed, gowns and caps for operators, and sterile towel or lid over the separator tank, negative cultures of the plasma immediately after separation can

be consistently obtained in an ordinary room. The few chance contaminants that might occur while separating the plasma under ordinary conditions are of absolutely no importance whatever if the plasma is run directly and continuously through a Seitz bacterial filter as described later. This point must be stressed in the practical working out of mass production methods in order to avoid the setting up of unnecessary requirements that would prohibit the very procedures essential to such production.

The rapid pooling of whole blood which we have previously described and had introduced into our routine in January, 1940, is not only necessary for large volume separation but is also desirable for two reasons. First, a completely neutral plasma free of agglutinins is obtained as a result of adsorption of agglutinins on corresponding red cells, second, agglutination of red corpuscles aids in the more complete separation of plasma resulting in a larger plasma yield. A yield of 50.3 per cent of true plasma was obtained upon careful measurement of amounts of blood pooled. Theoretically, the conventional centrifuge should approximate the hematocrit in yield. Actually, complete packing cannot be attained in reasonable time at the speeds available. Strumia, *et al.*,⁶ reported yields of 45 per cent at 2,000 revolutions per minute and a maximum yield of 54.8 per cent when centrifuging for forty-five minutes at 2,500 revolutions per minute in the large International No. 3 machine. However, a separation capacity of only twenty-eight to thirty-two bleedings could be realized in an eight-hour day, totaling 14 to 16 L. if 500 cc amounts were taken. Obviously, only the continuous separation principle has sufficient capacity per unit time for the volume of plasma that would be needed in wartime. For example, the smallest motor-driven separator of the type such as we employ has separated 25 L. of blood in thirty-five minutes. Larger separators of over 1,000 L. per hour capacity are available.

The plasma collects in a stainless metal container from which it is drawn through a sterile rubber tube into the reservoir of a Seitz filter. In a properly balanced system the plasma filters at about the same rate as the separation, thus making a closed continuous process. Any desired amount of plasma may be filtered by choice of a filter of suitable size. The filter disks can be obtained up to 2 feet in diameter. If for any reason part of the separated plasma cannot be filtered shortly after separation, it is sealed in stainless steel con-

tainers and kept frozen until it can be filtered. This technic conforms to our principle of never letting plasma or blood remain in the liquid state once the original vacuum seal of the collecting bottle has been broken.

Since only desiccation from the frozen state results in preservation of biologic properties, "flash" solubility, and indefinitely safe storage, a process utilizing this principle was deemed necessary. As described in an earlier paper,⁸ the adtevac process was worked out in answer to the need for a method of large-scale inexpensive desiccation. This process constitutes one of the four basic methods of dehydration from the frozen state, and its peculiar advantages for mass production are due to the utilization of controlled adsorption for the removal of water vapor under vacuum.

In actual large-scale use the process has proved to be economical and efficient. By this method the amount of plasma to be dried is limited only by the amount of adsorbent used and, since adsorbents such as silica gel have an indefinite life when properly handled, it is practical and economical to employ whatever amount the desired capacity requires.

Plasma may be dried in ampules, trays, or other containers according to the volume to be processed. In our hospital plasma service large pyrex ampules, containing up to 700 cc of plasma, have been used satisfactorily. Moisture analyses of the material dried for forty-eight hours show residual water to be as low as 0.03 per cent. Equally, dry plasma could be obtained in shorter periods if smaller amounts were placed in the ampules. Longer operation with larger loads are preferred to cut down labor required.

One of the most important features of our production methods has been bulk desiccation of plasma. This has reduced the technical problems of operation, such as the elimination of leaks in the system which tend to occur with the great numbers of connections necessary when processing in small original containers, but, more important, true mass production can be realized. Another great advantage of bulk desiccation is that a much larger quantity of the dry plasma can be placed in a given container. The final container can be practically filled with the granular dry plasma, yet because of its porosity an equal volume of water can easily be added or a vacuum is drawn in the final container and held by an adequately tight method of sealing. When used as a threefold or fourfold concentrate, the volume and weight of both the plasma and sterile water vials are much smaller than the equivalent

amount of whole plasma. A further advantage of the reduced volume is that an average dose may be given with an ordinary syringe. These advantages are particularly valuable for military use where simplicity, speed, and ease of transportation are essential.

Transfer of the dry plasma from the ampules to vaccine type vials is accomplished by a practically closed system using a sterile metal dispenser, a method to be described in another paper. The plasma is granulated, with reduced bulk and increased solubility resulting. A vacuum drawn through a needle is sealed by coating the rubber cap with celloidin.

In our earlier reports^{8,9,10} we described the preparation and use of four times concentrated plasma. The concentrate was prepared from dry plasma and kept frozen. Since preserving the plasma in dry form, we have standardized on 12.5- and 25-Gm doses to be dissolved in sterile pyrogen-free water and made up to 50 and 100 cc amounts, respectively, giving a solution between three and four times normal in concentration, depending on the figure taken for normal plasma.* These quantities were partly determined by the size of available vials.

Rapid or flash solubility of plasma, obtainable only when desiccated from the frozen state, is desirable as an indication of proper preparation and preservation and as a time-saver. The adtevac plasma, prepared and stored as described, dissolves to form the concentrated solution in an average time of two minutes with vigorous shaking. In some instances solution may be complete in as little as thirty seconds. By always administering the plasma immediately after dissolving, we entirely eliminate any opportunity for bacterial growth at any period from the time of drawing blood, through the processing of the plasma, and right up to the moment of administration. The extremely rapid solubility of adtevac plasma, together with the availability of different size doses, makes it completely unnecessary to keep the plasma in the liquid state, and instructions advise against this. However, it is of interest to note that tests indicate that the hypertonic plasma solution is bacteriostatic to most common contaminants.

*Note. Our four time concentrated plasma containing 25 Gm. of solids is equivalent to four times its volume of whole plasma containing approximately 20 per cent citrate solution. Protein content of the concentrate is from 18 to 20 Gm. per hundred cubic centimeters.

Reactions

The best criterion of the safety of plasma preparation methods is the reaction rate observed in actual clinical use. The most significant type is the febrile reaction. We feel that this manifestation is due to bacterial contamination and growth of some type, either pathogenic or nonpathogenic. In the latter group the pyrogenic bacteria are most important. Hemoglobin in plasma is not the cause of reactions. We have given plasma containing up to 1 per cent hemoglobin without untoward effects. This is to be expected in the light of the work of Ottenberg and Fox,¹¹ and Gilligan, Altschule and Katersky.¹² When using concentrated plasma stored in the frozen state, a reaction rate of 1 003 per cent was reported.¹⁰ Since our plasma has been stored dry as described above, no febrile reactions have been encountered in over 386 administrations. A few transient manifestations of other types were occasionally seen, such as urticaria, mild lumbar pain of brief duration, and slight pain over the vein during rapid administration. None of these phenomena were of clinical significance, all passed off quickly, with only mild complaints being registered and with no harmful effects resulting. The danger of vein thrombosis from concentrated plasma, as suggested by Brown and Mollison,¹³ has never been encountered in our series. The stimulating effect of hypertonic plasma on smooth muscle was seen in a few severe cases of shock where plasma administration to unconscious patients was followed by micturition or where stomachs were full by a mild type of regurgitation. These responses also noted by Brown and Mollison,¹³ were not of spasmodic character and in no case harmful to the patient.

Technical difficulties, such as sticking of syringe, excessive viscosity, etc., have not been encountered. Syringes stick only when a plasma of poor solubility is used. We have routinely employed a 50-cc syringe and 19-gauge needle without difficulty.

Clinical Uses

From the first we have advocated administration of the plasma in concentrated form in order to take advantage of the reduced bulk, as well as realizing therapeutic properties of the hypertonic solution. In some cases where the plasma was given as an intravenous protein food, it was simply added to other intravenous solutions.

For military use the advantages of desiccation and concentration take on new impor-

tance. If plasma can be given as far forward as the collecting station, as suggested by Kendrick,¹⁴ the factors of reduced bulk and perfect preservation under all conditions, together with the simplicity, speed, and effectiveness of administration of the concentrated form, should make this type of plasma therapy the treatment of choice in combating shock. For naval use the same characteristics are of utmost value because of restricted space, lengthy storage under all conditions, and the need for elimination of complicated systems employing carefully prepared tubing.

The effectiveness of concentrated plasma in shock therapy as observed in 45 closely studied cases was reported in another paper.¹⁰ Since most of those cases were associated with operations and possible hemorrhage, additional cases were studied in which other factors were primarily involved. Two cases herein reported illustrate the typical response to hypertonic plasma. Representing traumatic and neurogenic shock, these cases are of a type frequently encountered in warfare. Case 1 is illustrated graphically in Fig 1, Case 2 in Fig 2.

Case Reports

Case 1—A. M., a white man, aged 53, was admitted nine hours after an automobile accident. An examination showed the patient to be cold, perspiring profusely, pale with weak rapid pulse, and somewhat confused mentally. His left leg was in a splint, applied for comminuted fracture of the lower end of the femur. The right femur showed an intertrochanteric fracture. The blood pressure was 75 systolic and 64 diastolic, with pulse 130 and weak. The hemoglobin was 13.25 Gm. One hundred cubic centimeters of 4X adtevac plasma was given intravenously. In six minutes the sweating had ceased, the blood pressure was 96 systolic and 70 diastolic, and the pulse was strong, with a rate of 120. Hemoglobin at 11.75 Gm. showed the blood volume to be increased. Thirty minutes later another identical dose of hypertonic plasma was given, with the blood pressure rising to 100 systolic and 70 diastolic and the hemoglobin falling to 11.1 Gm. The blood pressure varied somewhat, remaining above the critical level, and at the end of twenty hours fell to 86 systolic, 64 diastolic, the hemoglobin was 13.75 Gm. One hundred cubic centimeters of 4X plasma elevated the blood pressure up to 116 systolic and 72 diastolic, and the increased blood volume was reflected in a hemoglobin of 8.5 Gm. No further drop in blood pressure was observed, and a transfusion of 500 cc of blood was given two hours after the last plasma. No further evidence of shock was observed and the patient recovered.

Case 2—S. S., a white woman, was admitted with gunshot wounds of the right and left

FIG 1

temporal and mandibular regions. Both eyes were markedly damaged. The patient was pale, could not be aroused, and did not respond to verbal or pain stimuli. Her veins were partly collapsed, her pulse was slow and weak, with slow respiration and no sweating. Her blood pressure was imperceptible, the hemoglobin was 15.5 Gm. Fifty cubic centimeters of 4X adtevac plasma was given by vein with a rise in blood pressure up to 104 systolic and 80 diastolic in thirty minutes. Response to pain was noted. The hemoglobin was 14.5 Gm. One hundred cubic centimeters of 4X plasma was then administered. In fifteen minutes the patient was asking for water and responding to pain. Her blood pressure was 118 systolic and 90 diastolic, and hemoglobin, 12.9 Gm. The patient was discharged six days later.

FIG 2

aged areas where large amounts of fluid and protein are fixed. However, desiccated plasma has a definite place—first, in order to store safely the large reserves needed for burns and, second, in order to use concentrated plasma in certain phases. The first point is of utmost importance in civilian, as well as military, practice. The enormous amounts needed in a few severe burn cases may deplete plasma supplies, and cases may be lost while more is being prepared. We have used plasma equivalent to over 10 L. of normal plasma in 1 extreme case. Hypertonic plasma also has a place for its instant availability and its initial rapid action where we have obtained excellent temporary results until provision for continuous administration of normal plasma could be set up. Such considerations might be of vital importance under air-raid conditions with numerous casualties. Finally, it has proved beneficial to be able to supplement the administration of normal plasma with occasional doses of the concentrate where hemoconcentration was remaining dangerously high and also to use the hypertonic form where the previous use of saline resulted in general edema, pulmonary edema, etc.

In the treatment of posthemorrhagic shock, hypertonic plasma is of definite value as a direct therapeutic agent and not merely a blood substitute. In this respect there is clinical and experimental evidence of three possible roles.

First, plasma alone may suffice even for relatively severe grades of shock where red cell volume has not reached a fatally critical level if adequate circulation can be restored to prevent anoxia. Here the hypertonic plasma, rapidly given, combats shock by immediate increase of blood volume and apparent contraction of vascular capacity, thus making red cell function more effective through accelerated circulation.

These cases show the same rapid favorable response to hypertonic plasma which was observed in our earlier series, and they indicate the availability and adequacy of interstitial body water to build up blood volume when the osmotic pressure of the blood is increased by the addition of concentrated plasma protein. The significant changes in the photoelectric hemoglobin determinations demonstrate the rapidity with which these blood volume changes occur. These cases also further support our thesis that the administration of concentrated rather than whole plasma is the treatment of choice in shock. The hemoconcentration that results in nonhemorrhagic forms of shock as a result of loss of fluid into tissue spaces is reversed to a large degree. Furthermore, direct stimulation of the vascular system seems to occur. A more rapid, as well as more physiologic, correction is thus approached. In such situations plasma is not a substitute but really a superior therapeutic weapon.

In burns, capillary damage is so extensive that little fluid can be withdrawn from dam-

Second, where red cell loss has reached the critical level mentioned above, plasma is still of great value when blood is not immediately available. The patient often can be kept alive until blood for transfusion can be obtained. In our experience this period in severe hemorrhage may be extended as long as one or more hours.

Third, even when adequate stores of blood are immediately available, hypertonic plasma should also be given, since circulation can be restored in this manner before the more slowly given blood can take effect. This combination is much more effective than blood alone. For example, in 1 case of ours where blood, given through three portals, was failing, the addition of hypertonic plasma reversed the unfavorable trend.

Conclusions

1 The methods employed in the desiccated plasma service of Baylor University Hospital are reported.

2 The experience gained from the preparation and use of desiccated plasma derived from 660,000 cc of blood during a twenty-month period of routine operation is discussed.

3 The complete safety of mass-production methods, including continuous separation of blood and bulk desiccation, is demonstrated in the freedom from febrile reactions and in the clinical results obtained.

4 The significance of these methods and results in military surgery is pointed out.

Discussion

Dr Paul W Searles, *Buffalo, New York*—The greatest disadvantages in the use of desiccated plasma has been in its preparation. The methods have been too cumbersome for the average-sized blood bank. However, Dr Hill has shown that it is possible for the average bank to produce a desiccated plasma.

The therapeutic value of plasma has been well proved. Certainly, where shock is not due to the loss of red blood cells plasma is indicated. There is also some evidence that plasma can be used in hemorrhage cases to carry the patient along until red cells are available.

It is quite a simple matter for the average bank to obtain whole plasma from blood. This whole plasma can be stored in bottles for a long time. I have used whole plasma in combating shock, however, concentrated plasma is interesting and deserves a fair trial.

The military value of the desiccated plasma cannot be overestimated. The simplicity of administering the plasma by syringe in the concentrated form is a definite advantage. There is the problem of transporting the sterile distilled water along with the desiccated plasma, which in the end means there is just as much bulk as in ordinary whole plasma. However, I do know that the use of desiccated plasma has been favorably considered by military authorities and will probably be adopted by them as their emergency method for treating shock.

The plasma prepared by Dr Hill's method has a slight reddish tinge. I understand that he attaches no importance to the traces of hemoglobin that may have been faced on centrifuging. As yet he has had no severe reactions because of this factor.

I was interested in the preservation of certain biologic properties that occur in the use of dried plasma. Ordinarily, we give freshly drawn blood or plasma to patients with severe infections.

Is it possible to preserve the immunity for any length of time in desiccated plasma?

INTERNATIONAL COLLEGE OF SURGEONS TO MEET IN MEXICO CITY

Pan-American unity in surgery as well as in hemispheric defense will be dramatically demonstrated when the International College of Surgeons holds its fourth international assembly in Mexico City, August 10 to 14.

Surgeons from most of the countries of the Western hemisphere and also England, Holland, Palestine, Portugal Switzerland, and Turkey

will participate. Many Pan-American countries are sending official representatives. Sessions will be conducted in both English and Spanish.

Especially emphasized will be military surgery and the lessons already learned from the Spanish Civil War, current British campaigns, and civilian experiences during air raids. Headquarters will be at the Hotel Reforma.

DEAFNESS IN CHILDREN

Early Detection, Management, and Treatment

EDMUND PRINCE FOWLER, M D , New York City

"SPEECH deafness" no matter what its degree has an effect upon the acquisition of language, education, employment, and emotional adjustment to the environment

In comparison to the extent to which deafness exists in the population, it is appalling how little is done to prevent it Ten per cent of the men recently applying for enlistment into the regular army were rejected because of noticeable "speech deafness" The testing of 1,200,000 public school children in New York City shows 4 per cent with hearing losses of 9 decibels or more for "speech hearing" This means that it requires about ten times more sound for these children to hear simple speech in a quiet schoolroom than for the normal hearing children and, in the usual noisy schoolroom, over a hundred times more intensity I estimate that one-third of all school children show losses of at least 15 decibels at some frequency Such losses, unless transitory, may mean "speech deafness" is to follow

The beginning of deafness is usually in youth, and it increases in severity with certain variations with age The old people who have no deafness for speech are those who escaped ear disorders in youth Deafness is almost the rule in professional swimmers and prize fighters and is inevitable under certain noise conditions such as long-continued exposure to open cockpit fighting planes, boiler factories, gun explosions, etc Deafness is common in people with an idiosyncrasy to certain drugs, especially quinine, salicylates, nicotine, etc

It is a mistake to imagine that just because an ear is slightly or even markedly deaf it is protected from noise Even severe nerve deafness does not offer protection from excessive noise In fact it increases the liability of damage from acoustic shock because the nerve elements are already damaged and are less resistant to trauma, and sound vibrations enter these ears just as readily as they enter normal ears

Man is especially exposed to acoustic shocks, and this is one reason why boys and men show,

Read before the Section on Pediatrics of The New York Academy of Medicine January 9 1941 including a demonstration by children from the New York League for the Hard of Hearing

on the average, a greater loss in the high tones than the girls and women and a more extensive nerve deafness later in life Boys love fire-crackers and cannons and to bat one another over the head They are fond of shooting One really bad acoustic shock may, and frequently does, rip some delicate structure in the middle or inner ear and cause hemorrhagic, exudative, or productive inflammations Even microscopic hemorrhages in the neural apparatus of hearing may cause extensive degeneration and deafness Deafness may follow concussion, without other neurologic signs.

Many diseases of childhood are associated with ear disease and disabling deafness, largely because of infections of the upper part of the respiratory tract The same bacterial irritant may produce different forms of inflammation, and the different irritants may produce the same anatomic forms of inflammation Little or nothing is known about deafness from the viral diseases

What should be done to protect the ear from the effects of the diseases and traumas of childhood? What should be done in the presence of deafness to conserve the residual hearing? Only a broad answer can be given here because the subject is too extensive I should say that the outstanding preventive measure is intelligent observation and testing Careful observation is in itself the acme of testing

When is it necessary to test the hearing, to find out if a child has any deafness, to determine whether he is merely hard of hearing or totally deaf? When is it necessary to undertake remedial or preventive measures or to consult an otologist? The primary responsibility for the correct answers to these questions rests upon the pediatrician The parents rely first on his advice

(1) Examine the newborn babies' external auditory meatuses for obstructions, congestions, secretion, pus, and blood If there is a history of congenital deafness in the family or if the gestation or birth has been abnormal, test every few weeks with simple noises Some advise waiting ten days or two weeks after birth before testing to allow time for the resorption of the gelatinous fetal pads and vascular tumefactions from the middle ears,

out because these do not cause total deafness delay is questionable on these grounds. At an early age it is difficult to set up definite tests and it is impossible to obtain quantitative results, but after five months (sometimes earlier) one may gradually condition the baby to respond to certain sounds, such as a bell or simple call words associated with something that makes for baby's gratifications—feeding or the desire for a toy, especially a toy that makes a noise. When the baby enjoys making the noise it is a sign that he is hearing it.

Some babies only a few weeks old will try to avoid a loud sound near the ear by moving the head. If this movement is consistently repeated, it is an excellent sign that the sounds at the intensities used have been heard. Use a tuning fork, bell, buzzer, etc. Be careful not to traumatize the ear by using sounds over 90 decibels above the normal threshold. The shouted voice two feet from the ear averages 80 to 100 decibels. If 80 decibels is not heard, "speech hearing" is usually lost. This means the child will be unable to acquire speech in the usual way.

Some babies will blink the eyelids or show a definite pupil reaction when, unexpectedly, they hear a fairly loud sound, such as loudly clapping the hands together. If these reactions are definitely and consistently obtainable without some other coincidentally acting stimulant confusing the picture, they may be accepted as a sign that the baby hears the sound used. Avoid using sound vibrations that can be felt instead of heard. When certain that any loud sound is heard, use fainter and fainter sounds to estimate roughly the degree of hearing. If unable to obtain pupillary or palpebral reflexes by sound alone, flash a small light before the baby's eyes simultaneously with the application of the sound. The eyes will blink to shut out the light. Repeat again and again until even when the light is not flashed the reflex will occur in anticipation of the light. The reflex is then a positive proof that the sound was heard. This is one conditioning procedure. Many others will suggest themselves to you.

Frequently, positive reactions may be elicited by applying a 512 or 256 vibrating tuning fork to the baby's skull. Notice if there is any difference in the reactions obtained when this is done and when a dead tuning fork is applied to the same spot. Often, if a baby is crying, he will stop crying abruptly on hearing the sound of a tuning fork before the ear or on the skull. His attention is concentrated on the new sensation. The lower

forks may be felt as well as heard, so that it is well to use the 512, which gives less surface sensation than the lower forks.

Babies who hear their own voices or even their own gurgling or bubbling and other simple sounds appear to enjoy their noises and, from time to time, will experiment by varying the pitch of the noises they are making. If a baby is backward in doing this or, when older, in imitating and in using simple sounds, the hearing in both ears may be at fault. To make sure, test it. Obviously, monaural deafness will not prevent the child from hearing himself.

Notice if the child always uses gestures to communicate with others. Older deaf and hard-of-hearing children do this whether or not they use vocal expressions. They seem to sense their vocal inadequacy. They think and signal in meaning rather than in words. A positive reaction to several of the tests described above will assure the presence of some hearing. How much, can be determined later. Place the source of the sound so that the child cannot see its manipulation.

Some day it may be practical to observe the acoustic reflex of the intratympanic muscles which occurs only with the hearing of sounds at least 40 decibels over threshold. We will then have a quantitative hearing test for even the youngest children.

(2) Keep in mind that potential deafness is hidden in most diseases of childhood and inspect ears, nose, and throat daily during their course. At the first sign of ear involvement, institute the indicated medical or surgical treatment and maintain it not only while the child is sick but also until the threat of deafness is removed. Keep in mind not only the cure of disease of the ear and of the body but also the preservation of the hearing.

The first noticed sign of ear disorder instead of a lowering of hearing may be stuffiness, head noises (tinnitus), vertigo, nausea or vomiting, or neurologic signs of meningeal irritation. Up to about 8 or 10 years of age, deafness is apt to be noticed only when bilateral.

In children, as well as in adults, head noises mean irritation and threaten destruction of the cochlea nerve apparatus.

(3) The hearing of every child should be carefully tested audiometrically on entering school and immediately following the diseases of childhood—also at six- to twelve-month intervals if teacher or parents suspect any hearing defect.

(4) Be sure that throughout childhood the

eustachian tubes are functioning physiologically. This is determined by otoscopic observations of the details of position and movability of the drum and other tympanic structures, not by forcible inflations of the middle ear, by air bag, or by catheter. Both politzerization and catheterization are much abused in youth and in later age. The catheter is practically never indicated in infancy or childhood.

If the ventilation of the middle ear is subnormal, some hearing will always be lost. The frequency regions primarily affected are the low-tone and the high-tone areas (64 to 512 and 4,000 to 16,000)¹. Which frequency is the more affected depends upon the amount and duration of the partial vacuum and the lesions in the middle ear and adjacent spaces. Every child should have a careful test to determine his normal hearing level even though there is no deafness. If in a previously tested ear no lowering of the hearing occurs at any frequency, the tube is functioning and inflations are usually contraindicated. A common symptom of eustachian tube dysfunction is ringing, clicking, or fullness in the ear. This is prone to recur with every cold. In the interim the hearing may appear normal.

(5) When necessary, and only when necessary, maintain ventilation of the middle ears by gentle air pressures (without traumatizing the tissues), and do not expect inflations at weekly or even daily intervals to maintain adequate ventilation or drainage until after the subsidence of the middle-ear and tubal blockage. Supplemental home treatment is needed in almost every instance to shorten the acute and subacute periods and to forestall a chronic aftermath—such as recurrent or chronic suppurative mucoid, or productive cicatricial otitis, and permanent deafness. The deafness may be missed unless the hearing is tested carefully.

I use hot saline ear douches before rupture or incision of the drum and, usually, gentle intermittent suction and a mild hot antiseptic douche during the resolution of the suppuration. I do not favor incision of the drum membrane unless it is seen that the eustachian tube is not sufficiently patent to permit the middle ear to free itself of secretion within a few days or unless the inflammation becomes purulent, causes prolonged pain, or threatens complications. I do not favor repeated drum incisions. If one, or at the most two, good incisions do not furnish sufficient drainage to control extension of the suppuration, the exudate is coming from spaces outside of the middle ear,

in the mastoid or petrous bone or eustachian tube, in which case a simple mastoidectomy is often indicated irrespective of the bacterial content of the pus. Simple mastoidectomy, unless delayed beyond the point where full recovery of middle-ear function can take place, is a surgical procedure that can be counted upon to restore and preserve the hearing to a greater degree than any other later treatment or operation. I am not impressed with the reported preventive action of sulfanilamide or other chemotherapy in uncomplicated acute or chronic otitis media, because we can show quite as good results without its use as with it. Sulfanilamide may be of distinct benefit locally if efficient drainage is established.

During recovery from all middle-ear and mastoid suppurations, the eustachian tubes and middle ears should be closely watched to insure timely treatment in case of their failure to function physiologically. Frequent careful testing of the hearing is a sensitive guide to these ends. It is quite commonly neglected. Instead the patient's word is accepted, and patients are easily misled as to changes in hearing.

In some instances the middle ear recovers and the hearing returns, but the infection becomes localized outside of the ear. Here the inflammation continues, usually as a mastoiditis. In such cases, simple mastoidectomy is indicated with no attempt to enter the middle ear by way of the antrum, aditus, or otherwise.

In little children the nasal sinuses, such as exist, are almost always involved with extensive head colds. The middle ear is one of the sinuses of the nose. The inflammation in the middle ear as well as in some other sinus may persist after the cold subsides—be sure to examine and test to determine whether or not this has occurred.

(6) Examine for, and remove, menacing lymphoid nasopharyngeal hypertrophies, especially those near the eustachian tubes. Do this under inspection, whether by surgery, diathermy, chemical cauterization, or irradiation—not by feeling and guessing. Restraint in the use of all these modalities will prevent overdestruction of mucous membranes and dry, crusty, and gobby chronic throats. It is not the mere presence of adenoids or hypertrophied lymphoid masses that threatens the hearing. It is their particular effects in the case in question. Only careful tests and often more than one examination will determine their true status and the advisability of their removal.

(7) Remove the tonsils if they are continu-

ally or often infected or if after 4 or 5 years of age it seems advisable in connection with adenoidectomy—not just because they are large or contain in their crypts some cheesy matter. Do not do this by blind clipping or burning. Do it by inspection and dissection so that you may be certain of a clean surgical removal of the tonsil, without including the palate, pillars, tongue, or other parts of the throat. The end results of many so-called tonsillectomies are worse than the results of leaving the tonsil *in situ*.

(8) A moderate recurrence of lymphoid tissue requires no treatment unless it takes on recurrent infections or is associated with a recurring hearing loss or nasal infections. The mere recurrence of lymphoid tissue is not *per se* a reason for repeated removal. More restraint is indicated in the removal of lymphoid recurrences than of the original adenoid masses. Every removal is followed by greater scarring of the throat. The persistence of the tendency to replace lymphoid tissue by little children suggests that this replacement may not be wholly useless. It aids in the maintenance of an efficient barrier to the spread of infection. A relative immunity appears to be closely related to this timely hypertrophy of the lymphoid barriers in the upper part of the respiratory tract of the child.

Irradiation of the nasopharynx to control lymphoid blocking of the eustachian tubes is sometimes warranted. It is one way to control lymphoid hypertrophies. It must be used with caution because it is not yet determined what the end results will be and what effect it will have on the healthful functioning of the mucous membranes involved. To avoid a too extensive destruction of tissue and to lessen the cost of using radon or x-ray, my son has devised a radium applicator that concentrates the effect of the irradiation closely to the region of the tube.

(9) Vitamin insufficiencies, even when corrected by natural or synthetic combinations, will not produce a healthy child unless there is sufficient and continued consumption and utilization of healthful food. Many fads and fancies always attend newly acquired remedial agents. The so-called biochemicals, under various names and combinations, now in vogue will in time give way to overemphasis on other and newer discoveries, and so on *ad infinitum*. You and I must use common sense in these matters if we are to best serve our young patients and, incidentally, their parents. The health and strength obtainable from a well-balanced diet of the old reliables throughout

the ages are still obtainable from the same old reliables today—milk, eggs, butter, cheese, whole wheat bread, cereals, meat, liver, leafy vegetables, tubers, oranges, and all the orchard, citrus, and other fruits. These foods obtained and consumed in sufficient bulk and in good environment will still produce healthy children. No synthetics will ever permanently take their place.

(10) Avoid meddlesome surgery and meddlesome medicine. Every patient is a law unto himself. This holds true in childhood as well as in youth and middle and old age. The practitioner knows by experience that even different members of the same family may react differently to similar diseases, they therefore need different management and treatment.

(11) There are several disorders and diseases causing deafness which strike so suddenly or so insidiously that we have been almost helpless to fend off their damage to the ear. I shall briefly discuss the deafness associated with heredity, meningitis, mumps, and syphilis.

Hereditary tendencies to several types of deafness may be shown, but environment in the largest sense is the more important etiologic factor. No immunity is so great that it can resist indefinitely repeated exposures to severe trauma or infection. Hereditary tendencies are ever present and, therefore, the family history may form an important background for all kinds of ear diseases and all types of deafnesses. But to state that a disease is hereditary does not explain its cause.

The neural apparatus of hearing is thought to be more often affected by hereditary influences than the conducting apparatus. This is probably because the neural machine in the cochlea and brain is more easily damaged by the local pressure, anoxia, or toxemia coincident to some diseases than the tougher mechanical apparatus in the middle ear.

One of the most prevalent forms of progressive deafness, beginning but not often discovered in youth, is otosclerosis. It usually shows a familial and hereditary background. A study of identical twins is being made, and it is hoped that it will throw some light on this subject. The cooperation of the pediatricians is desired in this work. If any of you know of twins of any age with otosclerosis or with a parent suffering from otosclerosis or progressive deafness, please arrange to have the children's hearing examined at least yearly. I will gladly contribute my services to this end.

It must be kept in mind that we tend to look and act like our forebears internally as well as externally, especially when the environment has been similar, and that we all, therefore, tend to take on similar ailments under similar provocations. The only immediate practical preventive measure is better environment. This includes better environment for preventing, as well as for throwing off, the disorder—in plain words, better prophylaxis, management, and treatment.

The only measure of service to prevent deafness from meningitis is anticipatory or early diagnosis of the meningitis, with prompt and efficient treatment by the newer methods of chemotherapy which offer much in preventing meningeal involvement of the eighth nerve. The only treatment is preventive because when the acoustic nerve elements are once degenerated or destroyed they never recover. To learn if the destruction is partial or total, careful hearing tests are necessary. To do this, the opposite ear must be excluded by masking, even though it, too, is severely deafened by nerve degeneration. The reason for doing this is because extremely loud sound will appear nearly or quite as loud to even a severely nerve-deafened ear as to a normal hearing ear. This is due to the presence of the "recruitment phenomenon."

A simple method for masking an ear is to blow steadily into the concha and external auditory meatus. Blowing across the open end of a rubber tube, the other end of which is in the ear, is also an efficient way of preventing an opposite ear from hearing the testing sounds. A stethoscope used monaurally is efficient for this purpose and is much less terrifying than the Bárány noise apparatus.

One reason why monaural deafness is not detected early is because the deaf ear is turned toward the sounds one desires to hear less than one-half of the time, and under many conversational conditions, even if the deaf ear is toward the speaker, there is a loss of only 15 to 20 decibels in the sounds reaching the good ear. This causes but little disability unless the good ear is masked by environmental sound or unless its hearing also is deficient. Environmental noise masks conversation more when the masking noise is on the side of the better hearing ear. There is, then, no opposite ear with which to hear.

No one knows how mumps causes deafness unless there is an associated meningitis or meningoencephalitis involving the eighth nerve. In many cases there is no such association, and yet the static, as well as the auditory

labyrinths, of the ear may be affected. The lesions accompanying mumps are usually unilateral, often total but sometimes unequally bilateral. They affect ears that were previously normal, as well as those showing any of the various degrees and types of deafness. A simple voice hearing test will usually suffice for a preliminary estimate of the extent of damage to "speech hearing." For a more accurate estimation, test both ears audiometrically by air and bone conduction. Masking of the opposite ear is usually indicated.

When monaural, the deafness from mumps in all my own cases has been on the side of the greater involvement. I wonder how often it occurs in atypical cases with no parotid involvement.

The only direct communication between the parotid gland and the inner ear is the channel occupied by the facial nerve. The pathway is not long, not much over an inch in all. It is suggested, since perineural inflammatory changes can travel along the course of nerves even greater distances than this, that in mumps this may be one mode of involvement of the inner ear.

Mumps is not primarily a suppurative inflammation—neither is the accompanying eighth nerve neuritis or labyrinthitis. The question arises. If the avenue of infection is the path of the seventh nerve, how does it happen that there is seldom a seventh nerve (facial) paralysis? One reason is that the seventh nerve is tougher than the eighth nerve. The auditory fibers are unmyelinated and are, therefore, more sensitive to poisons, anoxia, and pressure lesions. Pressure lesions in the internal auditory canal commonly irritate or paralyze the cochlea and the vestibular divisions of the eighth nerve without irritating or paralyzing the seventh nerve. The mumps infection being viral is not self-perpetuating like bacterial poisons. Toxic poisoning of the eighth nerve is common, of the seventh nerve, uncommon.

In little children, mumps is thought seldom to involve the ear, but after the age of 12 it does so more often than is realized. The symptoms of involvement, headache, temperature, tinnitus, vertigo, nystagmus, nausea, vomiting, or spastic paralysis in various combinations are often so slight that they are missed. When sudden and severe they are apt to be ascribed to the general bodily reaction to inflammation, to gastrointestinal disease, or to meningitis and not to the auditory or static labyrinth irritation or destruction. Their severity and sequence depend largely

ally or often infected or if after 4 or 5 years of age it seems advisable in connection with adenoidectomy—not just because they are large or contain in their crypts some cheesy matter. Do not do this by blind clipping or burning. Do it by inspection and dissection so that you may be certain of a clean surgical removal of the tonsil, without including the palate, pillars, tongue, or other parts of the throat. The end results of many so-called tonsillectomies are worse than the results of leaving the tonsil *in situ*.

(8) A moderate recurrence of lymphoid tissue requires no treatment unless it takes on recurrent infections or is associated with a recurring hearing loss or nasal infections. The mere recurrence of lymphoid tissue is not *per se* a reason for repeated removal. More restraint is indicated in the removal of lymphoid recurrences than of the original adenoid masses. Every removal is followed by greater scarring of the throat. The persistence of the tendency to replace lymphoid tissue by little children suggests that this replacement may not be wholly useless. It aids in the maintenance of an efficient barrier to the spread of infection. A relative immunity appears to be closely related to this timely hypertrophy of the lymphoid barriers in the upper part of the respiratory tract of the child.

Irradiation of the nasopharynx to control lymphoid blocking of the eustachian tubes is sometimes warranted. It is one way to control lymphoid hypertrophies. It must be used with caution because it is not yet determined what the end results will be and what effect it will have on the healthful functioning of the mucous membranes involved. To avoid a too extensive destruction of tissue and to lessen the cost of using radon or x-ray, my son has devised a radium applicator that concentrates the effect of the irradiation closely to the region of the tube.

(9) Vitamin insufficiencies, even when corrected by natural or synthetic combinations, will not produce a healthy child unless there is sufficient and continued consumption and utilization of healthful food. Many fads and fancies always attend newly acquired remedial agents. The so-called biochemicals, under various names and combinations, now in vogue will in time give way to overemphasis on other and newer discoveries, and so on *ad infinitum*. You and I must use common sense in these matters if we are to best serve our young patients and, incidentally, their parents. The health and strength obtainable from a well-balanced diet of the old reliables throughout

the ages are still obtainable from the same old reliables today—milk, eggs, butter, cheese, whole wheat bread, cereals, meat, liver, leafy vegetables, tubers, oranges, and all the orchard, citrus, and other fruits. These food obtained and consumed in sufficient bulk and in good environment will still produce healthy children. No synthetics will ever permanently take their place.

(10) Avoid meddlesome surgery and meddlesome medicine. Every patient is a law unto himself. This holds true in childhood as well as in youth and middle and old age. The practitioner knows by experience that even different members of the same family may react differently to similar diseases, they therefore need different management and treatment.

(11) There are several disorders and diseases causing deafness which strike so suddenly or so insidiously that we have been almost helpless to fend off their damage to the ear. I shall briefly discuss the deafness associated with heredity, meningitis, mumps, and syphilis.

Hereditary tendencies to several types of deafness may be shown, but environment in the largest sense is the more important etiologic factor. No immunity is so great that it can resist indefinitely repeated exposures to severe trauma or infection. Hereditary tendencies are ever present and, therefore, the family history may form an important background for all kinds of ear diseases and all types of deafness. But to state that a disease is hereditary does not explain its cause.

The neural apparatus of hearing is thought to be more often affected by hereditary influences than the conducting apparatus. This is probably because the neural machine in the cochlea and brain is more easily damaged by the local pressure, anoxia, or toxemia coincident to some diseases than the tougher mechanical apparatus in the middle ear.

One of the most prevalent forms of progressive deafness, beginning but not often discovered in youth, is otosclerosis. It usually shows a familial and hereditary background. A study of identical twins is being made, and it is hoped that it will throw some light on this subject. The cooperation of the pediatricians is desired in this work. If any of you know of twins of any age with otosclerosis or with a parent suffering from otosclerosis or progressive deafness, please arrange to have the children's hearing examined at least yearly. I will gladly contribute my services to this end.

ENORMOUS MYELOMENINGOCELE WITH FATAL LEAKAGE

Malformation at Foramen Magnum

ARTHUR D ECKER, M D , and J HOWARD FERGUSON, M D , Syracuse, New York

RECENT investigations have brought to clinical interest a long neglected anatomic syndrome. The Arnold-Chiari malformation consists of a downward prolongation of the cerebellum and medulla oblongata into the spinal canal, reversion of direction of obliquity of the upper cervical nerve roots, and extensive vascular adhesions in the subarachnoid space around the cerebellum. These abnormalities within the foramen magnum are almost always found in cases of myelomeningocele.^{1,2,3}

Recent workers have emphasized the danger of draining the sac because of the tendency of the malformed nervous system to act as a stopper at the foramen magnum. This effect explains those cases of hydrocephalus which follow aspiration or repair of myelomeningocele. The present case is reported to demonstrate both the huge size that such a sac may attain and the fact that death may ensue promptly after leakage from the sac as a result of the "stopper effect" with pressure on the medulla at the foramen magnum.

Review of Literature

This curious maldevelopment of the hind-brain was first recorded by Arnold in 1894. It was more fully described by Chiari in the following year. Later authors adopted the name "Arnold-Chiari malformation." In 1935 Russell and Donald⁴ described 10 consecutive examples of this malformation in cases of myelomeningocele and showed how the deformity may be the cause of the hydrocephalus. Their theory was that the Arnold-Chiari malformation plugs the upper cervical part of the spinal canal and hinders the upward flow of the fluid into the subarachnoid channels of the posterior fossa through which it normally passes on its way to escape from the cranial arachnoid villi. They suggested that if hydrocephalus were due to such malformation then air injected by the lumbar route would collect in the ventricles and not in the sulci of the cerebral convexities. Furthermore, they pointed out that such a finding would indicate the desirability of decompress-

ing the spinal cord at the foramen magnum. On the other hand, Graftdijk⁵ thought that the cerebrospinal fluid could escape upward into the ventricles or subarachnoid space but that there was difficulty in passing through the ventricles down into the vertebral canal.

Recently, Dr Dorothy Russell⁶ wrote of cases of myelomeningocele in all of which the Arnold-Chiari malformation was found. "Taking the group as a whole there seems to be a good deal of variation in the actual shape of this malformation, i.e., in the length of the cerebellar component, the extent to which both cerebellum and medulla protrude downward into the spinal canal, and so forth. And equally, I feel there is much variation in the degree of obstruction presented by this malformation at the foramen magnum. I should doubt whether it is ever absolute, but I feel convinced that it constitutes an effective blockage from the point of view of the development of hydrocephalus."

In a case of this syndrome, Jacob⁶ found circumscribed groups of misplaced cells in the cerebrum and cerebellum which he attributed to disturbances in migration in the course of embryonic development. He also described similar disturbances of development of the central nervous system in cases of microcephalus with feeble-mindedness and convulsions.

Surgical Intervention—D'Errico⁷ has demonstrated the Arnold-Chiari malformation in 10 consecutive cases of myelomeningocele in infants where hydrocephalus developed. He decompressed the foramen magnum in 8 cases with 1 operative death. However, within two years 2 patients died of hydrocephalus and 2 from apparently unrelated causes. Improvement followed operation on the malformation, whereas tension of the fontanels and increased growth of the head followed repair of the spina bifida. D'Errico considered the advisability of the suboccipital operation before the onset of hydrocephalus and stated that in those cases that do not respond to operation it is conceivable that additional abnormalities, such as atresia of the aqueduct, may be present.

Occasionally, exploration for posterior fossa tumor in adolescents or adults has revealed,

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 7, 1940.

From Syracuse University College of Medicine, Departments of Surgery (Prof. Albert G. Sault) and Pathology.

upon the speed and extent of the lesions. Deafness usually supervenes in the second week of mumps.

I have examined several children whose first symptom of ear involvement during mumps was tinnitus, increasing violent ringing or singing noises in the ear. Subsequently, they became deaf. Remember that tinnitus is always a warning of degeneration in the neural apparatus of hearing. Energetic measures are, therefore, warranted to prevent the deafness. It would appear that spinal puncture, phlebotomy, purging, or other measures to diminish intralabyrinthine pressure (choked labyrinth) and anoxia would be warranted in these cases. If applied early, the child is usually in good condition to stand them. They are also not without value for the threatening meningitis. I ask all pediatricians to look for tinnitus as a warning signal of the eighth nerve involvement. Unless diligently inquired for, the child will seldom call attention to tinnitus. The otologist needs the cooperation of the pediatrician who sees the child during the mumps. In this way lies progress for the prevention and treatment of mumps deafnesses.

Syphilis is greatly exaggerated as a cause of

acquired deafness in children. A positive Wassermann may be purely coincidental, but treatment by the arsenicals, although indicated, often endangers the ears. Total deafness may result not from the syphilis but from the drug.

I regret that I cannot bring to you a cure-all for deafness. That is, and always will be, impossible because deafness is only one symptom of many disorders and diseases of the body. I have stressed early and repeated testing. This is worthwhile for prevention and cure. The most satisfactory treatment will always be preventive. It is the most difficult to enforce.*

* Under the guidance of Miss Mary E. Van Horn of the New York League for the Hard of Hearing a demonstration was staged to illustrate some of the tests for hearing and some of the results obtained for little children by speech training, lip reading and hearing aids. It is believed that in the not distant future these aids for "speech hearing" will be used by all acoustically handicapped children in the regular classes of our public and private schools.

AMERICAN CONGRESS OF PHYSICAL THERAPY TO MEET IN SEPTEMBER

The twentieth annual scientific and clinical session of the American Congress of Physical Therapy will be held September 1 to 5, inclusive, 1941, at The Mayflower, Washington, D. C.

The mornings will be devoted to the annual instruction course, and the afternoons and evenings will be devoted to the scientific and clinical sessions. The seminar and convention proper will be open to all physicians and qualified technicians.

All the phases of physical medicine will be covered in the general program, including a special symposium on poliomyelitis. The program will be of interest to the general practitioner as well as to the specialist in physical therapy.

For information concerning the seminar and preliminary program of the convention proper, address the American Congress of Physical Therapy, 30 North Michigan Avenue, Chicago, Illinois.

At the same time the twenty-fifth annual meeting of the American Occupational Therapy Association will be held at The Mayflower. A combined meeting will be held on Wednesday, September 3, 1941. For information concerning the Occupational Therapy Association meeting, address Mrs. Meta R. Cobb, 175 Fifth Avenue, New York City.

EXAMINATIONS—AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

The next written examination and review of case histories (Part I) for Group B candidates will be held in various cities of the United States and Canada on Saturday, January 3, 1942, at 2:00 P.M. Candidates who successfully complete the Part I examinations proceed automatically to the Part II examinations held later in the year.

Applications for admission to Group B, Part I, examinations must be on file in the Secretary's office not later than October 6, 1941. Applications for Group A must be in the Secretary's office by March 1, 1942.

The general oral and pathologic examinations (Part II) for all candidates (Groups A and B) will be conducted by the entire Board, meeting at Atlantic City, New Jersey, immediately prior to the 1942 meeting of the American Medical Association.

As previously announced in the Board booklet, this fiscal year (1941-1942) of the Board marks the close of the two groups of classification of applicants for examination. Thereafter, the Board will have only one classification of candidates, and all will be required to take the Part I and Part II examinations.

For further information and application blanks, address Dr. Paul Titus, secretary, 1015 Highland Building, Pittsburgh (6), Pennsylvania.

hand which was held with the thumb everted and fingers flexed. Neither deep tendon reflexes nor plantar responses could be elicited in the lower limbs. The abdominal reflexes were present and equal. The biceps and triceps reflexes were normal. Pain sensations were clearly impaired in the lower limbs but could not be accurately tested. The skin over the pedicle of the myelomeningocele was normal but over the rest of the sac it was thin and shiny and contained large blood vessels. Three red ulcerated areas on the right side of the sac discharged fluid. No other abnormalities were revealed by physical examination.

FIG 3 Base of the brain. Tongue-like projection of left cerebellar lobe. Arrows mark groove caused by pressure on the foramen magnum.

On admittance the temperature was normal (99.6 F, by rectum) but promptly began to rise and continued to do so steadily for three days until the patient's death, at which time it was 103.8 F. The respiratory rate was 55 per minute on admittance, 90 per minute on the next day, and subsequently between 70 to 90 per minute. Although there was mild pharyngitis there was no dyspnea, coughing, or cyanosis. Examination of the urine yielded negative findings except for a minimal amount of albumin. Examination of the blood revealed normal findings.

Operative intervention, which had been contemplated as a palliative procedure, was deferred because of the fever and tachypnea. Since fluid was leaking from the sac it was thought best to aspirate most of it. Five thousand cubic centimeters of clear yellow fluid were obtained and found to contain 1 lymphocyte per cubic millimeter and 68 mg of total protein per hundred cubic centimeters. After the sac was aspirated, a firm bandage was wrapped around

FIG 4 Coronal sections of the brain. Dilatation of lateral ventricles, left more than right.

it and the patient's body in an attempt to minimize cerebellomedullary herniation at the foramen magnum, to which were attributed the rise in temperature and respiratory rate. Repeated examination of the thoracic and abdominal viscera revealed no abnormality. Specifically there was no evidence of pneumonia. On October 13 the respirations became progressively labored in the early evening, the extremities became cyanotic, and exitus occurred at 8:00 P.M. (four days after the beginning of leakage from the sac).

Necropsy was performed an hour later and revealed no abnormalities in the thoracic or abdominal viscera. The anterior fontanel measured 2 cm. in diameter, and there was some separation of the bones of the vault. The brain weighed 950 Gm. There was flattening of the convolutions of both cerebral hemispheres, and the third ventricle bulged ventrally. There was a tongue-like projection of the left cerebellar lobe into the foramen magnum and the upper part of the spinal canal which measured 6 cm. in length and 2 cm. in diameter (Fig 3). There was only minimal herniation of the right cerebellar tonsil into the foramen magnum. The caudal surface of the cerebellum and the ventral surface of the medulla were deeply grooved by the foramen magnum (Fig 3). There was a suggestion of a groove on the upper surface of the cerebellum which may have been caused by the pressure of the tentorium. There were many arachnoidal adhesions around the cerebellum.

The brain was sectioned after it had been fixed in formalin. There was marked dilatation of both lateral ventricles, the left more than the right (Fig 4), and moderate dilatation of the third ventricle. The aqueduct and fourth ven-

instead of a tumor, the Arnold-Chiari malformation of the hindbrain in partial development.^{2,7} Indeed, it is possible that this malformation may be present in most cases of congenital hydrocephalus

Case Report

This patient was referred by Dr R D Severance. At birth, on October 23, 1938, there was observed a swelling in the midline of the lumbar region, the size of a small grapefruit (approximately 45 cm. in circumference). It was noted at that time that the infant's left upper limb and both lower limbs were paralyzed. The motions of the head, neck, and right upper limb were apparently normal and no other abnormalities were discerned. The sac gradually grew in size. In May, 1939, when the patient was seven months old the circumference of the mass was $27\frac{1}{2}$ inches (69 cm). In July it was $46\frac{1}{2}$ inches (116.3 cm).

On September 21, 1939, the infant still suffered from paralysis of the left upper and both lower limbs. Both the fronto-occipital and suboccipitobregmatic circumferences of the skull were 45 cm. The sac of the myelomeningocele was greater than the child's trunk (Figs 1 and 2). The distance from the top of the shoulder to the buttock was 30 cm and from the upper

pole to the lower pole of the sac was 31 cm, from the right side to the left side of the pedicle of the sac, the distance measured around the infant's chest was 36 cm, but measured around the sac it was 57 cm. The distance around the sac from the upper part of the pedicle to the lower part was 73 cm. The pedicle was 11 cm long. The sac could be transilluminated. The weight of this sac of fluid, the size of a watermelon, kept the child anchored and prevented even its turning over. There were some areas of maceration on the right side of the sac. Arrangements for hospitalization were being made, when, on October 9, 1939, a small amount of watery discharge appeared at one of the macerated areas. The patient was brought to the University Hospital on the following day.

Physical examination on admittance revealed a head with prominent frontal and parietal bosses. The fronto-occipital circumference was 19 inches (47.5 cm). The scalp over the anterior fontanel was tense. The head was held backward but there was no stiffness of the neck. There was some asymmetry of the chest. The ribs on the right side seemed more prominent than those on the left, and the sternum was apparently on the left of the midline. The flaccid paralysis of both lower and the left upper extremities was essentially unchanged, although there was a little power in the grip of the left

way along the aqueduct by slight posterior dislocation of the brain stem with impingement against the edge of the tentorial notch

Discussion

Dr W H Hamby, *Buffalo, New York*—I would like to congratulate Dr Ecker upon his study of this case and to thank him for the photographs of this tremendous lesion. I have never seen one so large. The Arnold-Chiari malformation and its role in the production of hydrocephalus demonstrates how knowledge can be lost in the literature. It was not until Dorothy Russell reinvestigated the problem that the significance of this earlier work was appreciated. Dr D'Errico operated upon a series of these patients and demonstrated that the hydrocephalus could be arrested by repairing the malformation.

I have taken a conservative approach to this problem. Within the past five years we have repaired possibly 20 cases of meningocele and myelomeningocele of mild extent, without the occurrence of hydrocephalus and without fatality in any case. We consistently have rejected for operation patients with evidences of major involvement of cauda and feel that we have, thereby, acted in the best interest of our patients. I believe that in deciding upon advising surgery in these cases one must take into consideration more than the possibility of conserving a life by completing surgically the repair of an extensive lesion. One should take into consideration the effect upon the child, upon the parents, and the other children in the family—the preservation of the life of a patient who will spend his life in a wheel chair, developing and healing decubitus ulcers, and who will be an outcast from normal life because of nonfunctioning sphincters. This is a decision that should not be left with the parents entirely. They naturally are under an emotional strain that precludes good judgment, and they have no conception of the difficulties they will encounter. Where the lower cord or cauda is seriously involved, it is my impression that this is, par excellence, the situation where "it is better to make a whole new baby than to make a new baby whole."

Although I have not been able to obtain postmortem examinations on all children who have died with large myelomeningoceles, it has been my observation that those having hydrocephalus that was or was not recognized before death also had the Arnold-Chiari malformation.

Dr Tracy J Putnam, *New York City*—To me, the most important aspect of the case reported by Dr Ecker is the variety and multiplicity of the lesions present. It vividly illustrates the fact that serious congenital defects are usually multiple. The defects are not confined to any one germ layer or any one part of the body, as in this case they are present in the brain, the spinal cord and its meninges, and the vertebrae. Not infrequently there are abnormalities in the mouth, such as cleft palate, in the extremities, and in the intestinal tract as well.

When several defects occur together, the natural tendency is to classify the case as an example of the most striking one—in Dr Ecker's case, the meningocele. If we study a group of cases of malformations carefully, however, as he has done, we find some interesting correlations and transitions. That between hydrocephalus, spina bifida, and meningocele is well known. The relation between hydrocephalus, the Arnold-Chiari malformation, congenital dysplasias of the cerebellum, such as the Marie-Tooth syndrome, syringomyelia, and deformities of the base of the skull and cervical vertebrae are less familiar, but transitions may be found.

This presentation has several practical aspects. The first is that it is important to make a thorough investigation of every case of congenital malformation before deciding on a line of treatment. If the baby with a meningocele is paraplegic or imbecile, there is no use in operating on the meningocele no matter what its condition. The same principle needs to be applied even more rigidly to hydrocephalic infants, one can usually reduce the intraventricular pressure by operation in any case, but the infant is almost certain to succumb if there are other extensive cerebral defects. On the other hand, now that we have several effective types of treatment for hydrocephalus, operations for meningocele may be undertaken with more freedom.

In closing, I should like to point out one important method of distinguishing between internal and the so-called external hydrocephalus. Puncture of the ventricle produces a fluid containing little protein—less than 10 mg—unless it is infected, when, of course, it contains cells. Puncture of a subdural cyst, on the other hand, yields a fluid that is often yellowish and always contains a large amount of protein, usually over 200 mg. It is important to make a differentiation, as there is an effective treatment for each of these conditions.

Fig 5 Physiologic obstruction midway along aqueduct

tricle appeared normal in size, but the fourth ventricle was deformed by the pressure against the foramen magnum.

Between the twelfth thoracic vertebra and the sacrum the sac of the myelomeningocele presented. The skin and subcutaneous fat were dissected off and revealed a smaller sac of dura within which was a corresponding sac of arachnoid containing clear fluid. There was failure of union of the neural arches between the eleventh thoracic and first sacral vertebrae. On the right side there was a winglike posterior projection of the transverse processes and pedicles of the lumbar vertebrae. There was no evidence of pedicles or transverse processes on the left. The spinal cord was of normal diameter at the level of the twelfth thoracic vertebra, but, as it descended it became narrowed to the thickness of a shoestring. In the root of the meningocele the spinal cord became firm and bulbous, measuring 2 cm in diameter. Below this mass the filaments of the cauda equina came off. As the sac was being dissected off, the retroperitoneal space was entered on the left side.

Microscopic study revealed edema and some proliferation with acute swelling of the oligodendroglia in the cerebral cortex. In the cerebellum there was apparently an increased number of capillaries with thickened walls and some perivascular accumulations of the cells. The sections of the lower thoracic portion of the spinal cord revealed distortion of the normal structure as well as thickening of the pia. There was also perivascular fibrosis. The wall of the meningocele was thick and lined externally by skin, beneath which was fat and fibrous connective tissue. The inner lining of the meningocele contained a few islands of ependymal cells, some in true rosette formation. The tumor found at

the caudal end of the spinal cord was composed of encapsulated fat—that is, a lipoma—through and around which nerve fibers were passing. No group of misplaced cells was found in the cerebrum or cerebellum.

Comment

It was surprising to find marked internal hydrocephalus in this case, since the external diameter of the skull was practically normal, although it had increased in the last two weeks of life. The dilatation was limited to the third and lateral ventricles and was not present in the aqueduct or fourth ventricle. Necropsy revealed a pin-point opening between the aqueduct and third ventricle but no internal obstruction. There was some suggestion of grooving of the upper part of the cerebellum by the tentorium, and there may have been a block at the upper part of the aqueduct as a result of pressure of the brain stem against the tentorium.

One of us (A. D. E.) has demonstrated such a temporary block in a young adult with this condition by injecting a radio-opaque substance into the ventricular system supratentorially. Repeated roentgenograms (Fig 5) revealed that the substance was blocked about halfway down the aqueduct. At subsequent exploration of the posterior fossa which disclosed the Arnold-Chiari malformation, fluid injected into the lateral ventricle was freely recovered from the fourth ventricle and also found to contain some of the substance previously injected. It seems that with the original partial blockage of the outlets of the ventricular system in the posterior fossa there results the beginning of internal hydrocephalus, which may result in relatively greater dilatation of the anterior than posterior horns. The latter may result in slight posterior displacement of the brain stem with impingement against the edge of the tentorial notch. Thus, there results another point of blockage of the ventricular system—namely, midway along the course of the aqueduct.

Summary

There is reported a case of enormous myelomeningocele with fatal outcome soon after leakage from the sac began. The Arnold-Chiari malformation of the hindbrain was found and compression of the brain stem at the foramen magnum explained the fatal issue. There was dilatation of the third and lateral ventricles but the fourth ventricle and aqueduct were not dilated and the circumference of the skull was normal. It is suggested that there was a second point of obstruction mid-

Type of Patient

We observed a series of 30 patients over a period of about six months. Of these, 15 were cases of natural menopause, 9 were cases of artificial menopause (5 as a result of x-ray, 4 resulting from surgery), and 6 were those of early or impending menopause in which the patients were still menstruating but had menopausal symptoms.

The age average in the natural menopause cases was 50, in the artificial menopause cases, 39, and in the group of early menopause, 40.

The average duration of menopausal symptoms in all cases was three years—the longest duration being eight years and the shortest six months.

Symptoms

Flushes and sweats were the outstanding subjective symptoms in 22 cases and were present in lesser degree in the other 8.

Headache and vertigo were complained of by 23 of the patients and to some extent at one time or another in the other 7 cases.

Joint pains were a prominent symptom in 10 cases and were present in slight degree or of fleeting nature in many of the others.

Palpitation, precordial pain, and dyspnea were prominent symptoms in 10 cases.

Insomnia was a frequent symptom usually concurrent with flushes and sweats at night.

Psychic symptoms such as depression, "nervousness," crying spells, and other manifestations of emotional instability were present to some extent in most of the cases but were specially marked in 8 cases. Six of these had been diagnosed as psychoneurotics in other clinics, 1 as a case of conversion hysteria, and 1 as "neurasthenia."

Weakness, and lassitude were other symptoms occurring frequently.

Itching of the vulva was present in a marked degree in 2 cases, 1 of which had a severe vaginitis following x-ray sterilization.

Clinical Improvement

Flushes and Sweats—There was entire or almost entire relief from these symptoms in 19 cases and marked improvement in 8 others. In other words, a good clinical result was secured in 27, or 90 per cent, of the cases. Three patients were not at all, or only slightly, relieved of these symptoms (all of these were in the group in whom psychoneurotic symptoms were predominant).

Headache and Vertigo—These symptoms were greatly relieved in 3 patients (10 per

cent) and to a lesser degree in 8 (27 per cent).

Joint Pains—These were slightly relieved in 5 of 10 patients.

Psychic Symptoms—In the cases in which psychic symptoms were predominant, no effect could be seen with stilbestrol. Those demonstrating mild nervous symptoms obtained some relief.

Other Symptoms—Palpitation, precordial pain, dyspnea were slightly improved in a few cases. Weakness and lassitude were not affected.

Vaginitis and Kraurosis—The 1 patient with severe vaginitis did not take the medication long enough to observe any effect. One patient who had an early kraurosis vulva and complained of severe itching was only slightly relieved.

Blood Pressure—An attempt was made to ascertain the effect of stilbestrol therapy on blood pressure. Seven patients had, at first examination by us or at previous examinations by others, a hypertension (systolic over 150, diastolic over 100). Of these, 4 subsequently were found to be within normal limits. One other improved from 210/110 to 140/90. The other 23 patients retained their normal blood pressures during the treatment. We feel that where an improvement in blood pressure occurred it was due to the relief from the flushes, sweats, and insomnia rather than to any direct effect on the hypertension.

Our impression is that, in general, the greatest effect of the drug is to relieve the flushes and sweats and, as a result of this, to produce a subjective relief.

The time required to produce this improvement was in most cases about two weeks. In some cases marked improvement was noted by the patient within a week. In patients in whom the dose was subsequently reduced to 1 mg every two or three days, it was noted that in some the improvement could be maintained with such a reduced dose. One patient, suffering from severe menopausal symptoms following x-ray castration, received great relief within a week after therapy was begun. She continued to take stilbestrol for about four months, the dose gradually being decreased to 1 mg every five to seven days. The medication was then discontinued entirely, with no recurrence of menopausal symptoms in the two months' period to date. In other patients there was a recurrence or increase in severity of the symptoms when the dose was reduced, necessitating a return to the daily dose.

TREATMENT OF THE MENOPAUSE WITH SMALL DOSES OF STILBESTROL

SEYMOUR WIMPFHEIMER, M D , and LOUIS PORTNOY, M D , New York City

MANY investigators have reported their experiences with the use of stilbestrol, a synthetic estrogen. There is unanimity of opinion that the drug is a potent estrogenic agent and that clinically its effect is equal to that of the natural estrogens. Most authors emphasize the advantages of stilbestrol over the natural estrogens. These are its ease of administration, its efficacy when administered orally, its prompt action, and its low cost. There have been conflicting reports as to its toxicity. Shorr, Robinson, and Papanicolaou,¹ using an average daily dose of 2 to 4 mg, found that toxic symptoms occurred in 80 per cent of their patients. On the other hand, many investigators^{2,3,4} using the drug in similar or higher doses have not found so high an incidence of toxic manifestations or have noted that when toxic symptoms did occur they were usually of a mild or transitory nature. The varying doses used by different investigators, ranging from 0.1 to 30 mg and more daily, may account for these differences in toxic effects of the drug, although some authors are of the opinion that there is no parallelism between the size of the dose and the occurrence of the toxic symptoms. Individual susceptibility to the drug may be a factor in this connection.

We limited the dose given to our patients to a definite small amount—namely, a maximum of 1 mg a day. Administering this small dose to 30 patients, we noted the effect of the drug both clinically and upon vaginal smears, at the same time noting evidences of toxicity.

The chemical composition and properties of stilbestrol, a synthetic estrogen, were first described by Dodds, Goldberg, Lawson, and Robinson.⁵ In determining the estrogenic activity of diphenylethane and stilbene derivatives, these workers found the most potent of these to be 4,4'-dihydroxy- α,β -diethylstilbene, a derivative of 4,4'-dihydroxystilbene. This latter compound, which they found to be the mother substance of a series of estrogenic agents, was named stilbestrol. They found this compound ($C_{18}H_{20}O_2$) capable of ready synthesis and showed its structural resemblance to estrone ($C_{18}H_{26}O_2$). They also determined its potency to be two to

three times that of estrone and found that it was active when dissolved in oil or alcohol or in aqueous solution, as the sodium salt. Commercially, the drug can be prepared in forms suitable for administration by injection, by mouth, or percutaneously in ointment form. In our study we have used the drug by the oral route only in both tablet and gelatin capsule form.*

The drug is probably absorbed from the small intestine when given orally. The question has been brought up as to whether untoward symptoms, when they occur, arise as a result of local irritation or are of central origin. Some workers have found toxic effects to occur regardless of whether the drug was given by mouth or by injection, and, therefore, conclude that they are of central origin. Others⁴ have found untoward effects following oral administration which were absent or less pronounced when the drug was given by injection. Shorr and his co-workers have suspected that the drug causes toxic effects on the liver and have performed liver function tests on their patients to determine what impairment occurred. However, neither these workers nor others^{2,3,6} who have carried out liver function tests have been able to demonstrate any definite impairment of hepatic function in their patients.

Method of Treatment

We gave 30 patients stilbestrol by mouth in doses of 1 mg a day. Most of them received it in tablet form, several were given it in the form of capsules. Three of the patients were started with 2 mg a day, but this dose was not continued for more than one week. In many cases where there was improvement, the dose was reduced to 1 mg every other day and, in a few, to 1 mg every three days. The average length of treatment in 26 of the cases was thirteen weeks or an average total dose of 90 mg. One patient was given the drug continuously for thirty weeks, a total of 215 mg. Four patients took the drug for less than five weeks either because of intolerance to it or lack of cooperation.

* Stilbestrol (1 mg tablets) was supplied by Squibb and estrobenec (1 mg capsules) was supplied by Ayerst McKenna & Harrison. We wish to thank these firms for their cooperation in supplying us with the necessary material.

given her (stilbestrol, progynon DH, or sedatives)

Lassitude and drowsiness occurred in 4 patients, but it was difficult to evaluate these symptoms or to determine whether they were a result of the medication or part of the original illness for which the patients were being treated

Diarrhea occurred in 3 patients In 1 of these the attack was transient and may have been due to a dietary indiscretion In the 2 other patients diarrhea was noted in association with nausea One of the patients also complained of vomiting

Itching and dryness of the skin occurred in 2 patients but were so mild that the administration of the drug was not discontinued Urticaria occurred in 1 patient after she took the drug for seven weeks The medication was stopped and the rash disappeared

Summary

1 Thirty menopause patients who were treated with stilbestrol, in a dose of 1 mg a day orally for a length of time averaging about three months, were studied over a period of six months

2 Ninety per cent of the patients showed good clinical improvement, usually within a short time after the start of treatment

3 Vaginal smears were studied throughout the period of treatment In the majority of patients where the castrate type of smear was demonstrated, a change to the cornified type showing estrus reaction was noted Regression of the smears following a lapse in treatment could also be demonstrated

4 Uterine bleeding occurred in 13 of the 30 cases—in 8 during treatment and in 5 after, at its termination

5 Untoward symptoms resulting from the medication were not prominent Although 40 per cent of the patients complained of nausea

and heartburn at times, these were of a mild and transitory nature and did not necessitate withdrawal of the drug Four patients (14 per cent) refused to continue the drug because of alleged severe by-effects of a gastrointestinal nature

Conclusions

Stilbestrol is a potent estrogenic agent that effectively relieves the symptoms of the menopause An oral dose of 1 mg or less daily is sufficient to produce this beneficial effect With such a small dose, untoward symptoms when they occur are usually mild and transitory and do not require permanent withdrawal of the medication Although no definite toxic effects have been proved to the present time, the drug should be administered with caution and under strict supervision. The same limitations and contraindications that apply in the use of other estrogenic agents should be observed in regard to stilbestrol.

We feel that the efficacy of the drug and its ease of administration and low cost, together with the fact that when given in low doses it has thus far not shown any significant toxic effects, should make stilbestrol worthy of inclusion in our therapeutic armamentarium

MORE ARTFUL THAN ARTISTIC

In a letter to the *Medical Week*—the attention of physicians in the New York area, especially in Manhattan, is called to the following racket

A man who states that he is an artist and in dire need has been visiting the offices or homes of physicians in an attempt to sell paintings that he says he has painted. Without authorization, he uses the names of several physicians who are known for their interest in art and claims to have been referred by them He also states that he has been their art teacher

The physicians whose names he uses for reference have no information at all concerning this

artist He is unknown to most of them He has not taught any of them The only contact which they have had with him has been when he has approached some of them in order to sell them paintings He then uses their names without their consent when he approaches others. He makes a very forceful plea of poverty and sells these mediocre oils purely on a basis of charity

This statement should serve as a warning to physicians that this man is using the names of their colleagues without authorization. His story should be fully investigated before giving him any charity

Vaginal Smears

Vaginal smears were examined on our patients throughout the period of this study. Some of the smears were taken by us directly when the patient visited the clinic, but the majority of them were made by the patient herself at home and brought to us. It was quite easy to instruct patients to do this themselves, and the smears prepared by them were found to be adequate for study and classification. The advantage of this method was that in this way we could follow changes in the vaginal smear at frequent intervals, in most cases biweekly.

The typical vaginal smear of the untreated menopause patient has been described as one in which the cells present are small, with many leukocytes, cellular debris, and few, if any, of the large flat epithelial cells containing pyknotic nuclei which are characteristic of the vaginal smear of the woman with normal ovarian function. This typical menopause smear is designated as Reaction 1. The normal follicular phase of vaginal smear, in which essentially the only element seen is the large epithelial cell, extremely distinct, usually occurring in groups in regular alignment, with distinct cell borders and small nuclei is Reaction 4. Between Reactions 1 and 4 there are intermediate types which, according to the predominance of the types of cells and other elements present, are classified in this numerical way, as 1-2, 2, 2-3, 3, and 3-4.

Several of our cases demonstrate strikingly the effect of stilbestrol on the vaginal smear, showing a change from grade 1-2 to 3-4 within two weeks of treatment—these patients also had an associated prompt improvement in subjective symptoms. In most of the others where results were good the change in the vaginal smears was more gradual.

The typical menopause smear 1-2 was observed in 10 of our cases before treatment was begun. In all of these, with therapy, the smear changed to the follicular type, 3-4. Clinically, 8 of these patients obtained good improvement, 1 showed a fair result, and 1 showed no improvement.

Of the other 20 patients, 8 showed a follicular type of smear before treatment was begun, and in 12 no smears were obtained before instituting therapy. In these cases, however, the typical effect of estrogen therapy on the vaginal mucosa was demonstrated in the majority of instances in that there occurred a regression to the castrate type, 1-2, when treatment was discontinued and im-

provement to the follicular type, 3-4, when it was again resumed. These lapses in treatment, whether deliberate on our part or through neglect of the patient to return to the clinic for several weeks, usually also produced a concomitant recurrence or increase in severity of subjective symptoms.

To summarize, the relationship between clinical improvement and changes in the vaginal smear is as follows:

In 21 cases we found a parallel improvement in subjective symptoms and vaginal smears.

In 4 cases where, subjectively, the result was good there was no improvement in the type of smear.

In 2 cases there was an improvement in the vaginal smear but failure as far as the symptoms were concerned. (In both of these patients there was a large psychic factor.)

Three patients did not cooperate long enough to permit definite conclusions.

Vaginal Bleeding

Bleeding from the uterus occurred one or more times in 13 of the patients. In 5 it occurred after withdrawal of the medication and in 8 while medication was still being taken. In this regard it is interesting to observe that in the 2 instances where young women had had both adnexa removed vaginal bleeding occurred. Both these patients were incapacitated by marked menopausal symptoms and were affected mentally by their castration. Here, vaginal bleeding, simulating a period, produced a marked psychic improvement. In 1 case there was a period of bleeding lasting four days and, one month later, a recurrence of the vaginal bleeding. These patients had intact hymen so that endometrial or even vaginal studies were not feasible.

Whenever vaginal bleeding was reported the patient was examined to rule out any other possible cause such as fibroids or malignancy. In 1 patient with vaginal bleeding an endometrial biopsy revealed a hyperplasia of the endometrium.

Untoward Symptoms

Nausea was the most prominent untoward symptom. Twelve patients (40 per cent) complained of nausea at one time or another, but this was usually not severe and of transient nature. Four patients refused to take the medication because of a severe nausea. One of these was subsequently given the same drug in capsule instead of in tablet form without any complaint. Another highly neurotic patient manifested intolerance to any drug

CHART 1

CHART 2

sway continuing the proliferation of the endometrium into a secretory type, reaching its height premenstrually

The hormones, reaching a high concentration, inhibit the anterior pituitary, thereby causing a withdrawal of estrogen and progesterone which results in the breaking down of the superficial layer of the endometrium together with its bloody and mucous secretion. The latter is the external evidence of menstruation. This cycle repeats itself with the development of a new graafian follicle the following month and continues normally from puberty through the climacterium, except during pregnancy, lactation, and chronic diseases.

With this as a basis for normal function, let us discuss the most common forms of menstrual disturbances which you, as pediatricians, see in your female patients at the time of puberty. With each condition I shall attempt to show you the underlying pathology resulting from disturbances in the glandular makeup of the individual.

(1) *Amenorrhea*—The pediatrician is probably the first man consulted by a disturbed mother greatly concerned because her daughter has not menstruated. Secondary sexual changes have appeared, but there is no evidence of any menstrual discharge. An old-fashioned notion exists that amenorrhea at this time leads to tuberculosis. No greater fallacy has ever existed because the reverse is true—children with tuberculosis frequently do not menstruate.

Amenorrhea occurs for various reasons. First, congenital absence of the organs of the generative tract in whole or in part and, second, glandular disturbances. This paper concerns itself with the second group.

It is well known that all of the endocrines are interrelated through the anterior

lobe of the pituitary gland, the latter having thyrotropic, adrenotropic, and ovarian secretions. Therefore, with the disturbance of any one of these glands the others may be affected. In conjunction with the activity of the anterior lobe of the pituitary gland at puberty we find evidences of thyroid activity. This is displayed frequently in the adolescent girl by a temporary enlargement of the thyroid gland, spoken of as an adolescent goiter, which usually recedes after stabilization or iodine therapy. In many instances, this is an evidence of hypothyroid activity with its obesity, sluggishness, dry skin, lowered metabolism, and amenorrhea. It is plain to see that basically the disturbance is thyroid in nature and not ovarian, and the treatment, of course, is thyroid extract. This therapy is well known and its results speak for its efficacy.

Having ruled out a goodly proportion of amenorrhea cases at puberty because they are due to the thyroid activity, let us turn our attention to the other group that is due to disturbances in the ovary and pituitary body. Failure of either gland should be determined if possible. Estrogen determinations on the blood and urine can be done. If these are not available, vaginal smears can be used as an indication of ovarian activity. Albright¹² has modified the Aschheim-Zondek⁴ technic to determine the follicle-stimulating hormone as an indicator of pituitary activity. These two tests should aid in differentiating the faulty gland. Although the ovary and pituitary gland may exist in the body, it is quite possible that they may not function normally. It is possible that, even though the other secondary characteristics that denote ovarian activity have been developing,

THE PHYSIOLOGIC APPROACH TO THE ENDOCRINE TREATMENT OF MENSTRUAL DISORDERS OF PUBERTY

LOUIS A. SIEGEL, M D , Buffalo, New York

IN THE past twenty years medical progress has been directed toward the prevention of disease. This has been brought about by a better understanding of etiology, physiology, and pathology. In the infectious diseases, etiology has played an important role, leading to cures by attacking the cause of the infection or by substances to combat them.

In the group of functional disturbances, physiology has played a more important role. This has been especially true in the field of endocrinology. It was brought about by the discovery and isolation of new hormones which have led to a clearer understanding of the physiology of these glands. Investigation showed that we would have to change our ideas regarding the functions of some of the internally secreting glands, particularly the pituitary and sex glands. These glands we now know are especially concerned with the generative tract, and it is the purpose of this paper to discuss with you this newer physiology. This will give you a physiologic approach to the underlying causes of generative tract disturbances. With this in mind you should be able to select the proper hormone to be used in each type of disturbance.

As pediatricians, and following along the lines of prevention, disturbances in young girls before and during puberty should greatly interest you. You can do much to correct early abnormal physiologic functions so that your female patients will have a more normal adolescent period.

At the time of puberty secondary sexual changes have already started as evidenced by enlargement of the breast, appearance of hair suprapubically and in the axillae, changes in body contour, culminated by the appearance of the menstrual discharge. With menstruation established we assume that the child has now reached womanhood and is capable of reproduction. Many of the disturbances at this time concern the menstrual function, and I would, therefore, like to discuss briefly the newer theories of menstruation.

As shown in Chart 1 the pituitary body has become all important in the control of the sex glands. The anterior lobe of the pituitary body is directly responsible for the activity in

the ovary. I am excluding for many reasons the other functions of the anterior lobe since our topic is particularly concerned with menstrual disorders.

For matters of simplification let us start with the pituitary secretions, which we will divide into A and B. The pituitary A secretion is directly responsible for stimulating primordial follicles in their development into mature graafian follicles. The latter begin to develop at the time of puberty. Before this, the ovary remains fairly quiescent. The graafian follicle produces the basic ovarian hormone spoken of as the estrogenic hormone. This hormone affects the uterus and the endometrium. It is responsible for a proliferating thickened endometrium and sensitizes the uterine musculature to contractions. Ovulation, which also begins with puberty, results in the transformation of the ruptured graafian follicle into a fresh corpus luteum. This is brought about by a reversible action between estrogen concentration and pituitary A. When estrogen reaches a particular concentration, pituitary A is inhibited, allowing pituitary B to function. Pituitary B secretes a hormone that transforms the graafian follicle into a corpus luteum. This body has the property of producing chiefly another hormone, spoken of as progesterone, and a small quantity of estrogenic hormone. Its chief function is to continue the further growth of the endometrium as affected by the estrogenic hormone into a secretory hyperplastic membrane, reaching its highest development premenstrually. Its other function is to counteract uterine contractions that are initiated by estrogen.

Therefore, basically we have two hormones in the ovary, estrogen and progesterone, both being produced by stimulation of the anterior lobe of the pituitary gland. Let us for a moment discuss menstruation in the light of these hormones.

The cycle starts with the developing graafian follicle, which produces a proliferating endometrium. This continues until about midway in the interval between two periods, at which time ovulation occurs. The first half of the interval, therefore, is under the direct influence of estrogen. After ovulation the corpus luteum with its progesterone holds

sway continuing the proliferation of the endometrium into a secretory type, reaching its height premenstrually

The hormones, reaching a high concentration, inhibit the anterior pituitary, thereby causing a withdrawal of estrogen and progesterone which results in the breaking down of the superficial layer of the endometrium together with its bloody and mucous secretion. The latter is the external evidence of menstruation. This cycle repeats itself with the development of a new graafian follicle the following month and continues normally from puberty through the climacterium, except during pregnancy, lactation, and chronic diseases.

With this as a basis for normal function, let us discuss the most common forms of menstrual disturbances which you, as pediatricians, see in your female patients at the time of puberty. With each condition I shall attempt to show you the underlying pathology resulting from disturbances in the glandular makeup of the individual.

(1) *Amenorrhea*—The pediatrician is probably the first man consulted by a disturbed mother greatly concerned because her daughter has not menstruated. Secondary sexual changes have appeared, but there is no evidence of any menstrual discharge. An old-fashioned notion exists that amenorrhea at this time leads to tuberculosis. No greater fallacy has ever existed because the reverse is true—children with tuberculosis frequently do not menstruate.

Amenorrhea occurs for various reasons. First, congenital absence of the organs of the generative tract in whole or in part and, second, glandular disturbances. This paper concerns itself with the second group.

It is well known that all of the endocrines are interrelated through the anterior

lobe of the pituitary gland, the latter having thyrotropic, adrenotropic, and ovarian secretions. Therefore, with the disturbance of any one of these glands the others may be affected. In conjunction with the activity of the anterior lobe of the pituitary gland at puberty we find evidences of thyroid activity. This is displayed frequently in the adolescent girl by a temporary enlargement of the thyroid gland, spoken of as an adolescent goiter, which usually recedes after stabilization or iodine therapy. In many instances, this is an evidence of hypothyroid activity with its obesity, sluggishness, dry skin, lowered metabolism, and amenorrhea. It is plain to see that basically the disturbance is thyroid in nature and not ovarian, and the treatment, of course, is thyroid extract. This therapy is well known and its results speak for its efficacy.

Having ruled out a goodly proportion of amenorrhea cases at puberty because they are due to the thyroid activity, let us turn our attention to the other group that is due to disturbances in the ovary and pituitary body. Failure of either gland should be determined if possible. Estrogen determinations on the blood and urine can be done. If these are not available, vaginal smears can be used as an indication of ovarian activity. Albright¹² has modified the Aschheim-Zondek⁴ technic to determine the follicle-stimulating hormone as an indicator of pituitary activity. These two tests should aid in differentiating the faulty gland. Although the ovary and pituitary gland may exist in the body, it is quite possible that they may not function normally. It is possible that, even though the other secondary characteristics that denote ovarian activity have been developing,

CHART 3

the interrelationship between the anterior lobe of the pituitary gland and the ovary has not reached its full activity. It has been suggested that even though ovarian activity has started the function of ovulation may not be well established. We therefore should give it plenty of time to establish itself, and all of you have experienced cases of amenorrhea in young girls which have been cured by placebos and time. After a lapse of time (approximately one to two years) you are practically forced by the family to treat the amenorrhea. Although the ovary and its secretions are directly responsible for endometrial development and menstruation, the injection of ovarian substances will not produce stimulation of the ovary, because it is a well-known fact that injected hormones only substitute for, but do not stimulate, the mother gland. This, of course, means that should there be deficient ovarian tissue the injection of ovarian hormone would not be indicated. With large doses of estrogenic hormone it is possible to produce uterine bleeding but not true menstruation. We therefore must resort to the pituitary gland and its secretions to stimulate deficient ovarian tissue.

Today we have several substances that can be used for this purpose. Any active extract of the anterior lobe of the pituitary gland (prephysin and Armour's and Ayerst's preparations, etc.) or the extracts of pregnant mare's serum (gonadogen, gonadin, etc.) have the property of stimulating ovarian function. This has now been proved conclusively in both animals and humans.

It would therefore seem advisable that in cases of amenorrhea at the time of puberty, having ruled out thyroid deficiency, your treatment should be one of the above. These substances are so new that large series of cases have not been reported. Both these substances contain some impurities, and reactions should be watched. This is especially true of the products derived from pregnant mare's serum which contain small quantities of horse serum. I must, therefore, warn you as pediatricians that this newer generation has been subjected to varied injections of serum preparations for the prevention of contagious diseases and, if you are to use this product, you must test the skin of your patients for sensitivity. If they are sensitive, then you must desensitize them before using a full dose. In the anterior lobe extracts one may find reactions from a considerable quantity of foreign protein. These have not proved to be harmful. With improvement in the extraction of both substances the harmful elements should be eliminated.

Amenorrhea due to pituitary gland failure presents a difficult problem. Here, too, the use of anterior pituitary extracts may be tried.

(2) *Menorrhagia and Metrorrhagia*—Profuse and prolonged menstrual periods at the time of puberty, the so-called idiopathic juvenile bleeding, is a condition commonly seen by the pediatrician. The worried mother first consults the pediatrician because her daughter has shown signs of anemia, weakness, and prolonged bleeding. The periods usually are increased in duration and the bleeding may or may not be profuse.

Chart 2 will attempt to show you the pathology underlying this condition. In the upper half I have shown you the normal endocrine function of menstruation and in the lower part, the abnormal. We find that there is continued estrogenic stimulation. Behind this is a pituitary gland disturbance that has interrupted the ovarian-pituitary reversible reaction. There is no ovulation and, therefore, no corpus luteum formation (progesterone). Without this to mature the endo-

metrium, the latter continues to enlarge into a thickened hyperplastic membrane that breaks down and continues to bleed. There is no regular ovarian cycle.

Chart 3 shows you a microscopic picture of the normal endometrium in the second half of the interval. Chart 4 shows the endometrium characteristics of the juvenile type of bleeding. You will note the marked thickening as well as the cystic dilatation of glands forming the so-called Swiss cheese pattern found in this condition. The secretory phase is lacking and, therefore, the endometrium does not go through the normal cycle. The ovary, if looked at grossly, shows multiple small cysts, representing enlarged follicles with their increased estrogenic secretions. The restraining influence of the pituitary gland is missing. A corpus luteum is not to be found. You, no doubt, have had many instances where these young children have bled to the point of reducing their hemoglobin to 50, 40, and 30 per cent, thus necessitating transfusions. Many of these children have been curetted, some have been given small doses of radium with only temporary benefit. I have known of 2 cases in which hysterectomy was performed. The situation sometimes becomes serious, and transfusions, packing, and even curettage may be necessary to control the bleeding. One must exclude, of course, primary anemias, leukemias, purpuras, and other conditions that might be responsible for hemorrhage from any membrane in the body.

The treatment should be directed toward maturing these cystic follicles so that the endometrium could have the benefit of corpus luteum secretion. Pituitary B, the hormone that supposedly is responsible for corpus luteum formation, is not available as such. In the urine of pregnant women, however, there is a hormone called the anterior pituitary-like hormone. Thus, we believe, is derived from the chorionic epithelium of the placenta. In animal experimentation this substance has produced luteinization and hemorrhage in follicles.

Thus, it would seem reasonable to give anterior pituitary-like hormone, which appears on the market as antuitrin S, APL, folutein, antophysin, and others, but more recent work on humans has shown that these substances produce destructive changes in the ovary and should only be given with caution. Corpus luteum extracts such as progesterin, progesterone, lutein, etc., may be had. The results of the use of these substances

CHART 4

would be only temporary and have no effect upon the cystic ovary. It would seem more reasonable, therefore, to use products that would attempt to change the abnormal condition in the ovary. This would correct the faulty interrelationship between the pituitary gland and the ovary. Such substances as prephysin, gonadogen, gonadin, and Armour's and Ayerst's preparation might be used. Precautions in the use of these hormones have already been discussed. Recently, several articles have appeared on the use of testosterone propionate (male sex hormone) in profuse uterine bleeding. As a last resort this substance may be used. However, in children small doses should be used (10 to 20 mg per week) because the masculinizing effects, even though temporary, may be disconcerting.

(3) *Dysmenorrhea*—Primary dysmenorrhea occurring with the onset of menstruation is extremely common, and its treatment still remains as perplexing as ever.

The new endocrines can now be added to the pages of remedies formerly used. Many of the older ones produced their effects by psychologic reactions. Others have been analgesic or have produced sedation. In the chart explaining menstruation (Chart 1) it is pointed out that estrogen has the power of sensitizing the uterine muscle to contractions and also inhibits the anterior lobe of the pituitary gland when it has reached sufficient concentration. On the other hand, progesterone was found to have a sedative effect upon the uterus with its resultant relaxation of the uterine musculature. The cramplike intermittent pains at the time of menstruation suggest excessive uterine contractions.

Two courses of treatment are therefore open to us. We can give enough estrogenic hormone to inhibit the anterior lobe of the pituitary gland, which in turn would inhibit

estrogen formation, or we can use large doses of progesterone to relax the uterine muscles so that it could not respond to estrogenic stimulation

More recently, there have been many converts to the estrogenic therapy. Injections of estrogenic hormone are started postmenstrually and are given throughout the month, individualizing the size of the dose to get the effect. Five thousand units given two or three times weekly throughout the cycle may be used to begin with, but the dose may be varied or lowered as is found necessary. Testosterone propionate with its inhibiting effect on ovarian activity has also been recommended. I should advise strongly against its use at the adolescent period because I do not believe it should be used before the ovary has stabilized itself.

Progesterone given before the onset of menstruation should theoretically relieve dysmenorrhea. Progesterone, proluton, progestin, lutein, and others are marketed. These products are still too expensive to be used freely. Mouth preparations of corpus luteum hormone have recently been introduced and, if they prove active, may be used for this purpose.

Meigs¹² in a personal communication feels that corpus luteum extracts seem to produce more pain at the periods, and he advocates the use of large doses of estrogenic hormone. My own practical experience with some form of atropine has proved as beneficial as some of the endocrine products. Given for two or three days before the onset of the period, it seems to reduce or modify the pain.

For the past two years a new synthetic substance called diethylstilbestrol (stilbestrol) which as yet is not on the market, has been used experimentally in place of estrogenic hormone. It is approximately two and one-half times stronger than estrogen, as 1 milligram corresponds to approximately 25,000 International Units. Even though it produces nausea and vomiting in approximately 25 per cent of cases it is worthwhile trying in dysmenorrhea. Children tolerate the drug very much better than adults and a milligram given every other day throughout the month has been used. No large series of cases have been studied to make any definite report.

(4) *Precocity*—The appearance of secondary sex characteristics and menstruation in children under 10 years of age is not common in this part of the country, and its appearance in younger children should be looked upon as

abnormal. More recently, it has been shown that granulosa cell tumors of the ovary are responsible for this condition. These cases bear watching and, if enlarged ovaries can be felt, surgery may be required.

When these conditions are associated with hirsutism and deepening of the voice, tumors of the adrenal gland must be suspected. Where growth has been impaired in these precocious children, x-ray of the long bones should be used to observe the epiphyseal line. If there is any tendency to closure, large doses of anterior pituitary growth hormone should be used to stimulate a more normal stature.

(5) *Vaginitis*—Gonorrheal vaginitis in children before puberty is well on its way toward being relegated to the definitely cured group. The work of Lewis¹ has brought out the theoretical basis for this cure. It was found with the use of estrogenic hormone the epithelium of the vagina was transformed into a thickened, mature, adult form. The infection being situated in the superficial layers of the vagina was easily thrown off. Te Linde² has published a fairly large series. This work has been corroborated by other groups. The hormone is given by vaginal suppository, mouth or injection, with good results (theelin, amniotin, estrone, etc.). More recently, cases treated at the Buffalo Children's Hospital have been receiving stilbestrol with the following results. One milligram of stilbestrol was given three times daily by mouth, and after seventy-two hours all smears and cultures were negative and all patients were discharged within a week. This is a marked improvement over the old method of treatment as well as being of benefit to the hospital in reducing the length of hospitalization. Te Linde⁴ has reported good results with stilbestrol suppositories.

Conclusions

The physiologic approach to the endocrine treatment of gynecologic conditions found at the time of puberty has been discussed. An attempt was made to show you the underlying cause of each condition so that your treatment would be directed toward it.

1. In amenorrhea of endocrine origin an attempt should be made to diagnose the deficient gland. Thyroid should be used in cases showing a lowered basal metabolic rate. In ovarian failure hormones extracted from the anterior lobe of the pituitary gland and pregnant mare's serum, both of which stimulate the ovary to more normal function,

should be used. Pituitary gland failure presents a difficult problem.

2 In menorrhagia and metrorrhagia, so-called juvenile bleeding or juvenile hyperplasia of the endometrium, overactivity of follicle hormone is the basic cause. The Swiss cheese type of hyperplasia of the endometrium is found. Hormones from the anterior lobe of the pituitary gland or pregnant mare's serum should be used to correct this dysfunction. The cautious use of testosterone propionate (male sex hormone) is recommended only where other measures have failed.

3 In dysmenorrhea, estrogenic hormone given throughout the month in adequate dosage should be tried. In other cases corpus luteum given premenstrually may inhibit excessive uterine contractions. Belladonna in some form may give equally satisfactory relief. Stilbestrol should make its appearance on the market shortly and can be used as a more potent estrogenic substance. It should be given throughout the month in adequate dosage.

4 Precocity.—Granulosa cell tumors of the ovary and tumors of the adrenal gland may be responsible for this condition. Careful study may help to differentiate these cases. Anterior pituitary growth hormone should be used if there is any attempt at closure of the epiphyseal lines leading to short stature.

5 In vaginitis, the efficacy of estrogenic hormone cannot be questioned. Stilbestrol however, because of its potency as well as its inexpensiveness, produces excellent results within a week.

6 In spite of the small amount of horse serum in the hormone produced from pregnant mare's serum, all patients should be skin tested for sensitivity to this substance—children, especially so, because of the greater incidence of injections for immunity. In the anterior pituitary extracts, reactions from foreign protein may be encountered. However, these are not of any serious nature.

PUBLIC HEALTH RESEARCH INSTITUTE OF NEW YORK CITY, INC

The setup of the new Public Health Research Institute of New York City, Inc., for which an appropriation of \$100,000 is included in the 1941-1942 budget of the Health Department, to be used exclusively for scientific research essential for the protection and the improvement of the health, safety, and welfare of the people of New York City, was announced by Health Commissioner John L. Rice on June 28.

"Many public health problems that arise in this city," said Mayor F. H. LaGuardia in commenting on the Board of Estimate's approval of the contract between the city and the Research Institute, "are peculiar to this locality and scientific research and experimentation with regard thereto must be done locally. In this the largest city in the world, disease may readily assume epidemic proportions and thus it is most essential that our municipal Health Department be fortified with the best research talent and facilities available. The Research Institute will make that possible."

The Board of Directors of the Research Council has named as president David M. Heyman, a member of the banking firm of Adolph Lewisohn and Sons, president of the New York Foundation, and a member of the Board of Health. David

Rockefeller was made vice-president, David Morse, secretary, and Edwin P. Chumlund, treasurer.

A Research Council has been set up by the Board and is headed by Thomas M. Rivers, M.D., director of the Hospital of the Rockefeller Institute for Medical Research. Other medical men and scientists named to the Research Council are Eugene L. Opie, M.D., professor of pathology, Cornell University Medical College, Henry Clapp Sherman, Ph.D., professor of chemistry, Columbia University, Michael Heidelberger, Ph.D., associate professor of biochemistry of the College of Physicians and Surgeons, Columbia, George Baehr, M.D., clinical professor of medicine of the College of Physicians and Surgeons, Ralph S. Muckenfuss, M.D., director of the Bureau of Laboratories of the Department of Health, is a member ex officio.

Neither members of the Board of Directors nor of the Research Council will receive salaries. The Institute will be housed in the Health Department's Bureau of Laboratories which is located in the William H. H. Hallock Park Laboratory at the foot of East 15th Street, New York City.

MESENTERIC CYSTS

Review of Literature, Genesis, and Classification Report of a Case

MARTIN J LOEB, M D , New York City

BETWEEN the two layers of the mesentery the lymphatics drain the intestines. Efferent vessels drain the chyle to the glands and eventually bring it to the receptaculum chyli, and there, too, the blood vessels carry the blood to and away from the intestines. Aberrant thyroid, ovarian, splenic, liver, etc., tissues, which may be found anywhere in the body, may also migrate and remain between the layers of the mesentery. In the developing embryo, retroperitoneal organs such as the wolffian body and duct, the müllerian body, and the germinal epithelium may leave remnants behind the peritoneum which become displaced forward between the two layers of the mesentery. Sequestrations from the vitelline duct or from diverticula of the intestines, which according to Lewis and Thyng¹ are of regular occurrence in the embryos of the pig, rabbit, and man, may be found in this mesenteric space. (The term "mesenteric space" in this paper is applied to the space between the two layers of the mesentery.) Ordinarily, this space is filled with some 50 to 150 lymph vessels, the superior mesenteric artery, and its numerous branches that supply the small intestine. Lymph glands as well as fatty tissue are also found in this mesenteric space. As the layers of the mesentery are separated, the space becomes larger. This happens when a cyst or new growth invades the locality. In addition to this, infections such as the echinococcus, the tubercle bacillus, etc., may invade the space. The echinococcus will form a cyst. Gould² states that tuberculous glands may caseate and form a cold abscess and, if the patient develops resistance, the abscess will become encapsulated and in this way form a mesenteric cyst.

From the connective tissue in the mesenteric space, solid tumors, mainly sarcomas, develop. Rausohof and Friedlander³ state that sarcomas arising from the mesenteric tissue are usually of the spindle cell variety, while sarcomas that develop retroperitoneally and are pushed forward between the two layers of the mesentery are composed of small or large round cells. Carcinomas may develop from the intestines and invade the space

or may develop from epithelial tissue remnants within the space.

The genesis of cysts and tumors is necessarily associated with the factors mentioned above. It is well to remember these facts in the classification of cysts and tumors of the mesentery. Mesenteric cysts are not surgical rarities. They are, however, of sufficiently uncommon occurrence to be of interest to the surgeon and physician.

Historical

Beneviene,⁴ a Florentine anatomist, in 1507 reported a mesenteric cyst that he found on the autopsy table. Subsequent to that, tumors or cysts of the mesentery were reported from time to time. All these were from autopsy or dissecting material.

In the early and middle part of the last century, Horsius, Tophius, Balonius, de Ruysch, and Morgagni from time to time reported cases found on the autopsy table.

Braquehay⁵ in his extensive monograph divides the history of mesenteric cysts into three periods.

- 1 From Beneviene to 1850, during which time all the reports were made from autopsy material.

- 2 From 1850 to 1880 these tumors were occasionally met on the operating table. The preoperative diagnosis of other conditions such as intestinal obstruction or ovarian tumors were made.

- 3 From 1880 on, when Pean, Tillaux, Millard, Merklen, and some German surgeons made these tumors better known in the medical literature. Operative cases were reported and a preoperative diagnosis was occasionally made. Tillaux and Millard described the clinical symptoms, Merklen described the pathology, and Pean described the surgical treatment that he used, which was that of marsupialization. It is interesting to note that Panas⁶ in 1852 reported a case of mesenteric cyst which he cured by puncture.

Ney and Wilkinson⁷ suggested a fourth period commencing in 1900, at which time Dowd⁸ published his paper and promulgated the theory that these cysts are embryonic in origin.

TABLE—DIAGRAM

(1) Embryonic Cysts	(A)	Enterostomas of intestinal origin from	Either of these by the extravasation of lymph may become
	(1)	Sequestration during development (omphalomesenteric duct or embryonic diverticula)	
	(2)	Persistent Meckel's diverticulum	(1) A chylous cyst. By extravasation of blood
(B)	(1)	Embryomas spring from retroperitoneal organs within mesenteric space	(2) A hematogenous cyst. By malignant degeneration
			(3) A malignant cyst
(2) Teratomatous Cysts	(1)	Arise from misplaced ovarian tissue in the mesenteric space	
(3) Infectious Cysts	(1)	Caused by	
			(1) Echinococcus
			(2) Tubercle bacilli
	(2)	Encapsulated abscess between the two layers of the mesentery	

Frequency

It is difficult to give a true estimate of the frequency of mesenteric cysts, since a number of the reported cases were not sufficiently clear and detailed to include them definitely among the number.

Augagner⁸ in 1886 reported 90 cases of mesenteric tumors of which 18 were cysts. Arekion⁹ in 1891 referred to 81 reported cases of mesenteric cysts. Braquehay⁶ in 1892 collected 23 more cases and stated that solid tumors are about twice as frequent as are mesenteric cysts. Judd (quoted by Roller¹⁰) reported 25 cases of mesenteric tumors in 820,000 admissions to the Mayo Clinic, 8 of the 25 were cysts. It is interesting to note that both Judd and Braquehay report the same proportion of mesenteric cysts to mesenteric tumors. The Children's Hospital of Los Angeles reported 3 cases in three and one-half years out of a total of 12,425 admissions.¹⁰

Our case is the only one that occurred in the Bronx Hospital out of a total admission of 105,000 cases. Because of the rarity and the capricious distribution of these tumors, some surgeons may never meet a case while others may have several. The *Index Medicus* for the last several years, lists references to about 8 to 10 case reports a year. With this as an index and Braquehay's report of 1892 as a base, there should be about 550 to 600 cases reported up to now.

Definition

A true mesenteric cyst occurs between the two layers of the mesentery or beneath the serosa of the intestine. It is not malignant, dermoid, or parasitic. It does not arise from any normally placed retroperitoneal organ or from embryonic rests, although it may have grown and pushed its way into the mesenteric space.

Genesis and Classification

Tumors or cysts of the mesentery must necessarily originate from the structures either normally or abnormally situated in the mesenteric space. Numerous classifications have been made beginning with Portal,¹¹ Braquehay,⁶ Moynihan,¹² Dowd,³ Niosi,¹³ and many others. These classifications have succeeded in causing confusion in the mind of the reader. The theory of Dowd at the present time is generally accepted and falls in line very well with Dowd's classification. It seems to me that this classification with certain additions or modifications should serve to convey to the reader the conception of genesis and appearance of these cysts.

Dowd classifies mesenteric cysts into (1) embryonic cysts, (2) hydatid cysts, and (3) cystic malignant disease.

Niosi subdivided this classification into (1) cysts of intestinal origin, (2) dermoid cysts, and (3) cysts of retroperitoneal organs.

It is to be noted that this classification is not based on the definition given. It includes growths in the mesenteric space other than true mesenteric cysts.

Using the classifications of Dowd and Niosi as a basis and taking into consideration Dowd's view that chylous or hematogenous cysts are preformed cysts in which chyle or blood accumulated, I constructed a table which I believe is a simple classification and in all possibility a true one (see above).

Cysts are formed by the retention of the secretion within these structures. Des Gouttes and Sicord¹⁴ report a case in which the cyst was lined by intestinal mucosa and seemed to be of intestinal formation. Swartley¹⁵ also reports such a case. That the cellular structure of cysts vary is no argument to discard the theory, since inflammatory conditions to which all tissue is heir may change the epithelium lining to scar tissue (Swartley). Niosi¹³

MESENTERIC CYSTS

The *Index Medicus* for the last several years, lists references to about 8 to 10 case reports a year. With this as an index and Braquehay's report of 1892 as a base, there should be about 550 to 600 cases reported up to now.

Definition

A true mesenteric cyst occurs between the two layers of the mesentery or beneath the serosa of the intestine. It is not malignant, dermoid or parasitic. It does not arise from an normally placed retroperitoneal organ or from embryonic rests, although it may have grown and pushed its way into the mesenteric space.

Genesis and Classification

Tumors or cysts of the mesentery must necessarily originate from the structures either normally or abnormally situated in the mesenteric space. Numerous classifications have been made beginning with Portal,¹¹ Braquehay,⁶ Moynihan,¹² Dowd,⁸ Niosi,¹³ and many others. These classifications have succeeded in causing confusion in the mind of the reader. The theory of Dowd at the present time is generally accepted and falls in line very well with Dowd's classification. It seems to me that this classification with certain additions or modifications should serve to convey to the reader the conception of genesis and appearance of these cysts.

Dowd classifies mesenteric cysts into (1) embryonic cysts, (2) hydatid cysts, and (3) cystic malignant disease.

Niosi subdivided this classification into (1) cysts of intestinal origin, (2) dermoid cysts, and (3) cysts of retroperitoneal organs.

It is to be noted that this classification is not based on the definition given. It includes growths in the mesenteric space other than true mesenteric cysts.

Using the classifications of Dowd and Niosi as a basis and taking into consideration Dowd's view that chylous or hematogenous cysts are preformed cysts in which chyle or blood accumulated, I constructed a table which I believe is a simple classification and in all possibility a true one (see above).

Cysts are formed by the retention of the secretion within these structures. Des Gouttes and Sicord¹⁴ report a case in which the cyst was lined by intestinal mucosa and seemed to be of intestinal formation. Smartly,¹⁵ also reports such a case. That the cellular structure of cysts vary is no argument to discard the theory, since inflammatory conditions to which all tissue is heir may change the epithelium lining to scar tissue (Smartly). Niosi¹³

collected 5 cases of cysts in the mesenteric space arising from urogenital embryonic tissue. Higgins and Lloyd¹⁶ state that a teratomatous cyst was never found in a male patient. Ney and Wilkinson⁷ noted that all mesenteric teratomas reported have occurred in women. The conclusion to be drawn therefrom is that these arise from misplaced ovarian tissue. Gould² reports several cases of mesenteric cysts which he attributes to encapsulated tubercular abscess.

Location

Lewis and Thyng¹ found thirty-three "pockets" or diverticula in an embryo of 23 mm. In an older embryo they found forty-eight such pockets. These diverticula in the embryo occurred in the small intestine.

Wallmann (quoted by Higgins and Lloyd¹⁶) found thirty-seven diverticula in a piece of small intestine 48 cm. long, and thirty of these were between the layers of the mesentery. He also found some present in the large intestine. The duodenum is perhaps the commonest location, and it is said that diverticula occur there frequently. Since the intestinal diverticula do occur in the human embryo, they might become separated from their origin and form true mesenteric cysts. If a cyst should develop from any of these sequestered embryonal diverticula, they might be found near any part of the small intestine or even the large intestine.

If the cyst develops from the vitelline duct or Meckel's diverticulum, the cyst arising from the former will be high up in the intestine while the latter would be in the mesenteric space near the lower part of the ileum. Cysts arising from urogenital embryonic tissue may be found anywhere in the mesenteric space, usually, however, in the region of the ileum.

Diagnosis and Symptomatology

Braquehay,⁵ as was mentioned at the beginning of this paper, in his historical division of mesenteric cysts, designates the third period as the beginning of preoperative diagnosis and operative surgery. If diagnoses were made then on these symptomless cysts, our surgical ancestors were much better than we are. Since the diagnosis must depend upon symptoms and since symptoms are so indefinite and x-ray findings practically negative, a diagnosis in the early stages is impossible. Later on when the tumor causes such complications as intestinal obstruction, peritonitis, and hemorrhage, the symptoms of the complication will mask the original cause and one intervenes

because of the complication. Before any complication arises, however, one may be able to make a diagnosis of a cyst within the abdominal cavity if the mass is palpable. But then there would be other symptoms such as pressure symptoms to call attention to the mass.

The symptoms will depend upon the size of the tumor, the location of the tumor, and the pressure it exerts on the intestinal canal and on the surrounding tissues and blood vessels.

Objective Signs

The objective signs in the later stages will be (1) a tumor located in the mid-abdomen, which is movable and cystic and surrounded by tympanic areas. (2) X-ray. Occasionally the tumor will show a shadow on the x-ray. If this is contrasted with a barium meal, one may make a diagnosis. (In our case our x-ray resident, Dr. Goldblum, outlined a shadow on the plate preoperatively. We did not, however, do a gastrointestinal series.)

Symptoms

Symptoms are those of the complication. If there is a partial intestinal obstruction, it will cause a colicky pain, paroxysmal in character, and vomiting. If the intestinal obstruction is acute, the diagnosis will be made by the symptoms of the obstruction and the x-ray plate will show gas in the small intestine. (In our case the x-ray plate showed gas in the small intestine.)

Complication

(1) Intestinal obstruction. The tumor may grow around the intestinal cavity and strangle the gut within its embrace causing a subacute or acute intestinal obstruction. This occurs in 40 to 50 per cent of the cases.

(2) Peritonitis may occur either as a sequel to intestinal obstruction or because of rupture of the cyst into the peritoneal cavity.

(3) Hemorrhage, sloughing of a blood vessel within the cyst cavity, may cause a fatal hemorrhage within the cyst.

(4) Torsion of the cyst.

(5) Incarceration of the cyst within pelvic cavity.

Treatment

a. Enucleation is the treatment of choice. This, however, cannot always be done.

b. If the intestines are strangled within the cyst, resection of the cyst with the stran-

gulated intestines should be done with a side-to-side or an end-to-end anastomosis

c Marsupialization is the treatment for patients who are poor risks and in whom the cyst cannot be attacked in any other way. The mortality varies. It is the highest in cyst and intestinal resection, where it reaches from 35 to 50 per cent.

Case Report

E. B., a white girl, aged 14, was admitted to the hospital on January 13, 1938. Her chief complaints on admission were recurrent vomiting and abdominal pain for five days. The character of the pain was sharp, colicky, and intermittent, and was localized to the center of the abdomen. After an emetic attack the pain would be localized to the left upper quadrant. She had bowel movements and enemas that yielded good fecal material. There was no history of blood or mucus in the stools or of an infectious process. Her menstrual history was negative.

A physical examination revealed a normally developed female child who did not appear acutely ill, in fact, between attacks she seemed quite at ease. Her heart and lungs were negative. The abdomen was distended but not markedly so. There was a dull percussion note over the mid-abdomen. No rigidity or distinct masses were palpable. Eye, ear, nose, and throat were negative except that there was no conjunctival reflex. Her blood pressure was 124/80. The temperature ranged between 99 to 100 F. The general appearance of the patient was that of a shy girl of introvert personality.

Laboratory Data—Her urine was negative on two occasions. The blood chemistry was within normal range. Icteric index was 147. There was a direct delayed van den Bergh reaction. The indirect van den Bergh test showed 12 units per hundred cubic centimeters of serum. The white blood count was 16,000, with 70 per cent polymorphonuclears and 11 band forms. The rest was normal.

An x-ray examination demonstrated the distention of small bowel with gas. The large bowel was collapsed. A faint shadow on the plate the size of a grapefruit was interpreted as an intra-abdominal mass. A diagnosis of subacute intestinal obstruction of unknown etiology was made.

The patient was given 5 per cent glucose solution intravenously and repeated small enemas. Wangansteen drainage (small bowel), as well as local measures such as rectal tube, turpentine stupes, gastric lavage, etc., were given to relieve distention. Enemas gave good results. Gastric lavage yielded some coffee-ground material. There was no occult blood in gastric contents nor was there any fecal material present. The medical treatment was given in the hope that it might help the intestinal obstruction, if it was caused by a kink, to adjust itself.

Since no improvement was noted, the patient was operated on January 17, 1938, four days after admission to the hospital.

Operation Inner Right Rectus Incision—On opening the peritoneum a great deal of serous fluid was found, which was suctioned. A large mass was present in the abdomen and about 6 inches of the small intestine was entangled and imbedded in this mass. The proximal part of the small intestine was completely occluded and distended. The distal end was collapsed. The large, yellow, soft mass, having a cystic consistency, sprang from the mesentery. The entire mass was delivered outside the abdomen. The intestines were clamped about 6 inches away from the mass and resected with the cautery. The mesentery, which was hemorrhagic and congested, was also resected on either side of the cyst. The intestines were closed by inverted sutures and two layers of Lembert's sutures. A side-to-side anastomosis was then done. Several sutures were inserted in the mesentery to bring it together. A drain was inserted to the anastomosis and the abdomen was closed in layers.

Postoperative Diagnosis—Intestinal obstruction caused by mesenteric cyst.

Postoperative Treatment—Continuous Wangansteen drainage for decompression of the bowel and slow intravenous drip of 5 per cent glucose solution were instituted postoperatively. The child made an uneventful recovery. She showed an immediate postoperative elevation of temperature to 101.4 F for two days. On the sixth postoperative day the child moved her bowels spontaneously and was discharged on February 2, 1938, with the wound healed, her bowels moving regularly, her temperature normal, and a regular ward diet being maintained without embarrassment.

A one-year follow-up reveals the patient in good condition and not presenting undue symptoms.

Pathology—Gross specimen consists of two separate loops of ileum, measuring 32 and 15 cm in length, respectively. The first of these consists of a U-shaped loop of bowel, connected and maintained in shape by mesenteric adhesions. From this area there project six or seven cysts, the largest 8 cm in diameter and the smallest 2.5 cm in diameter. On opening them we found some distended with chylous fluid and some with a yellowish oily fluid. There are found two cysts, one on each side of the mesentery, that connect with each other and another similar set of two. The other three or four cysts are single and are located on either side. The surface of one of the cysts is covered with multiple thrombosed veins. For a distance of 12 cm the ileum is dilated, the wall is thin, and the valvulae conniventes are absent and sharply demarcated from the remainder of the intestine. At both ends of this portion of the ileum the intestine is normal in size and ap-

FIG 1 Unopened mesenteric cysts with attached ileum

FIG 3 Wall of the cyst consists of vascularized connective tissue and fat, the latter exhibiting perivascular round-cell infiltration

FIG 2 Large mesenteric cyst opened showing the smooth lining. There is no connection with the lumen of the bowel

pearance, although at one end the ileum appears to be sharply twisted on itself.

The second portion of ileum appears normal except for a 15-cm blackish brown area extending from the mucosa to the serosa.

Microscopic section taken through the wall of the cyst exhibits a vascularized connective tissue and fat, with a focal area of perivascular round-cell infiltration.

It is apparent that the specimen described above belongs to the chylous type of mesenteric cyst. These may be large, single, and multicolor or small and multiple. The contents may consist of clear fluid, chyle, or fat. It is my im-

pression that this type of cyst belongs to the group of lymphangomas. The absence of smooth muscle fibers definitely identifies this case as belonging to the chyle cyst group rather than enteric cyst. (See Figs 1, 2, and 3 *)

Comment

I saw this child in consultation with Dr Gurvitch two days before admission to the hospital. My first examination at home revealed no distention or tenderness of the abdomen. No mass was felt and the abdomen was flaccid and apparently normal. The child expelled gas by rectum. Because of the peculiar psychologic makeup of the child, the anesthesia of the conjunctiva, etc., I was of the opinion that there was a possible hysterical element in the picture.

After the second day the distention appeared, the expulsion of flatus diminished, the vomiting continued and, above all, the x-ray revealed gas in the small intestine. During all this time the child did not appear to be acutely ill. It is significant that the percussion of the distended abdomen was dull rather than tympanic, and as time progressed there was a resistance to the touch if not real rigidity.

* I am indebted to Dr Joseph Felsen for assistance in preparing the illustrations.

Summary

1 A résumé of literature and discussion of the genesis of cysts are hereby appended

2 The classification of Dowd and Niosi is newly interpreted

3 A case of a cyst within the mesenteric space is reported

MEDICAL AID TO CHINA

American financial help has assisted in the creation in China of one of the most remarkable medical relief corps existing in any warring country, according to Dr Donald D Van Slyke, president of the American Bureau for Medical Aid to China.

Scores of mobile medical units that are situated close to the Chinese fighting lines, and that can be dismantled and moved within an hour's notice, form the heart of the Chinese Red Cross Relief Corps. The medical staff attached to these medical units totals 2,800, and of this number about 1,200 men and women serve as stretcher bearers.

The Chinese Red Cross Medical Relief Corps was organized by Scottish-trained Dr Robert K S Lim, who served for three years with the Indian Medical Unit in France during the first World War.

When Dr Lim joined the Red Cross at the outbreak of the war, soldiers wounded by bullets or shrapnel were dying before medical attention could reach them and as many died from malnutrition as from bullets. Dr Lim has changed that picture. He organized the Medical Corps into mobile operating, nursing, and preventive units. The preventive unit carried out a health and antiepidemic program, sterilizing water, setting up delousing plants, inoculating soldiers, and civilians alike against cholera, malaria, typhoid. Operating and nursing units worked close behind the front lines, so that wounded soldiers had first-aid care before starting their journey to base hospitals—often a stretcher journey many days away because of the existing roadless areas. Rest stations were set up every ten miles to provide shelter, food, water, and fresh dressings for wounds.

In the spring of 1938 came an urgent cable from Dr Lim, asking for 4,000,000 doses of vaccine to fight an outbreak of cholera. Within twenty-four hours, funds had been raised to purchase a million doses from an American firm in Hongkong. Delivery of the full amount was completed in three weeks. The epidemic was

checked. As a result of this practical American sympathy and aid, cholera in China last summer was almost nonexistent.

Since then, the American Bureau has sent tons of quinine to Dr Lim and to the Chinese Red Cross and, more recently, has sent quantities of atabrine, the new malaria remedy. To date, about 85 per cent of all his medical supplies and more than 90 per cent of his ambulances and supply trucks have been supplied by overseas Chinese and by donations from abroad.

The American Bureau for Medical Aid to China has sent 159 ambulances and has provided gasoline and spare parts to keep them running.

One of the Medical Corps' most interesting activities has been encouragement given to farmers to remain on their farms growing crops even though these farms lie close behind the fighting zone. In many sectors, half the food for the Chinese soldiers is being produced in the war area itself.

"It is almost certain," said Dr Van Slyke "that the invader counted on a high casualty rate among the Chinese because of inadequate medical attention. The Japanese cannot afford to have more than 1,000,000 in China, for they cannot take men out of industry or away from the Russian border. So, you see, Dr Lim's work in caring for the wounded Chinese soldier, and in sending him back into the fight is an upsetting factor to the Japanese."

"The Chinese death rate has been whittled down by other American aid in the form of ambulances, vitamins, and trucks for evacuation work. In speeding such help, the United China Relief has done much to sustain Old China long enough for Dr Lim and others like him to create the new Free China."

Beginning July 1, The American Bureau for Medical Aid to China, through United China Relief, will send \$5,000 a month to China, to support Dr Lim's training schools and orthopedic centers, and to supplement the contributions of the American Red Cross.

Crowded living conditions, mounting prices of necessities, increased mental, emotional and physical strain—inevitable byproducts of in-

dustrial defense activities—are factors dangerously favorable to the increase and spread of tuberculosis.—Kendall Emerson, M D

EARLY DIAGNOSIS OF PULMONARY TUBERCULOSIS

WILLIAM L. WEINTRAUB, M D , Paterson, New Jersey

THE most important single feature in the diagnosis of pulmonary tuberculosis is to bear the disease in mind and remember its frequency. In the age group of 15 to 45 years it continues as the leading cause of death. According to conditions in 1930, the estimated frequency is that, of 1,000 white men born, 42.5 will eventually die of tuberculosis, and, of 1,000 negro men, 96.7 will die.

In spite of this great frequency most of the patients already have extensive disease when first diagnosed. This represents a challenge to medicine. The key to the solution probably lies in the hands of the general practitioner. He sees all the patients.

We know that a definite number of those who are ill proceed to advanced disease rapidly, however, this is not true of the majority and is certainly not the rule. Symptoms may be absent even in the presence of considerable active pulmonary tuberculosis, this again is not true of the majority. The patients in whom the above is true, of course, cannot be diagnosed or even suspected earlier by the general practitioner but must, if at all, be discovered through popularization of public health procedures, such as contact examinations and periodic examinations of groups suggested by our knowledge of the occurrence of the disease. There remains a goodly percentage, in fact the majority, of morbidity which we believe is diagnosable much earlier than is being done at present.

There are four main procedures ordinarily utilized in the diagnosis of disease, and tuberculosis is no exception. (1) history, (2) physical examination, (3) laboratory procedures, and (4) x-ray examination.

The history is always important. A history of contact is especially important. The symptoms may be divided into two groups: (1) constitutional or general symptoms that occur because of absorption of focal products and (2) focal or local symptoms that occur because of the local irritating or destructive effects of the lesion. Under the general group may be listed tired feeling, weakness, loss of weight, chills, fever, sweats, loss of appetite, stomach disturbances, nervousness, increased pulse rate, pallor, etc. Under the local group may be listed cough, sputum, blood-spitting,

pulmonary hemorrhage, chest pain, pleurisy with effusion, hoarseness, aphonia, difficulty in swallowing, rupture of the lung, rectal abscess, alternating diarrhea and constipation, dyspnea, etc. The modes of onset are various. Pulmonary tuberculosis may begin with any one of the above-named symptoms or any possible combination of two or more. In point of time the onset may be insidious or acute. It may begin as a pneumonia, indistinguishable clinically from any other pneumonia, or as a grippe, influenza, common cold with or without fever, etc. There is nothing in the symptomatology which spells tuberculosis. The constitutional symptoms may be found in any constitutional disease. The local symptoms may be found in any disease that can produce similar local irritation or destruction. The history can point definitely to tuberculosis, can be highly or mildly suggestive, but cannot of itself establish either the presence or absence of clinical pulmonary tuberculosis.

Physical examination of the patient is relatively of little value in ruling out the possibility of pulmonary tuberculosis. The general findings such as wasting, emaciation, flushed cheeks, fever, rapid pulse, low blood pressure, etc., may constitute a clear-cut clinical picture but assuredly tax no one's diagnostic acumen in the presented patient. They are all late signs, and the symptomatology in practically all instances will already have directed attention to pulmonary tuberculosis as the provisional diagnosis. There may be considerable pulmonary involvement with no positive chest findings. The inability to elicit abnormal chest physical signs certainly does not diagnose the absence of pulmonary tuberculosis and is of no great value in ruling out the disease in a given patient. Positive findings, especially cavernous signs or persistent moist rales over the upper third, clearly indicate serious chest disease. However, from physical examination alone the probable pathologic picture cannot at all be prognosticated with any degree of accuracy except in an extensive destructive disease that constitutes no diagnostic problem. Patients with visual evidence of pulmonary involvement, such as rib thatching, contracture, scoliosis, again present no diagnostic problem. Positive chest signs do not diagnose

Consulting physician for chest diseases, St. Mary's Hospital, Passaic, New Jersey

tuberculosis as the etiology. They may make it probable or most likely, but more evidence than that is procurable and warranted to make a diagnosis such as pulmonary tuberculosis. The same physical signs may occur with active and inactive or healed involvement.

Laboratory methods ordinarily employed are examination of the sputum for tubercle bacilli and the tuberculin test. Limiting the scope of this presentation to pulmonary tuberculosis leaves out of consideration the examination of other body tissues and secretions as in extrapulmonary lesions. The tuberculin test is not a test of active disease in its clinical sense. A positive reaction shows the sensitivity of the reactor to tuberculo-protein and indicates that the individual harbors within his tissues viable tubercle bacilli. Such an observation does not indicate that the individual has clinical tuberculosis or that existing symptoms are due to tuberculosis. A negative reaction with certain reservations is reasonable assurance that the individual is not sensitive to tuberculo-protein and that his tissues are free of tubercle bacilli. In a negative fashion this test is valuable and is not sufficiently employed by the general practitioner. Its most important field of use, however, is in children and the public health practice, a subject by itself and beyond the intended scope of this article. The sputum may be positive very early but is usually a late manifestation, and the diagnosis should be made in most cases long before the sputum is positive. Examinations should be made daily for several days, utilizing the morning sputum. A negative sputum is, of course, of no value by itself in ruling out pulmonary tuberculosis. However, a good diagnostic point is that given a patient with suggestive clinical symptoms who raises considerable purulent sputum that on repeated examination, including concentration tests, is persistently negative it is advisable to seek another etiology for the symptoms, since they are most likely not due to pulmonary tuberculosis. There are occasional exceptions, and also the above presupposes atypical or inconclusive x-ray findings. Examination of the sputum is beyond a doubt often a sadly neglected procedure, and its increased employment would diagnose many cases of pulmonary tuberculosis much earlier than is being done at present. Sedimentation tests and blood counts have their place but are not of great importance in the ordinary case from the standpoint of the general practitioner and early diagnosis.

X-ray examination has revolutionized chest

diagnosis. In fact, much of the modern pathologic concept of pulmonary tuberculosis has been developed through the study of serial x-ray films and could have been demonstrated in no other fashion. Living tissue pathology is observed through its various changes by serial films. X-ray alone shows the extent of involvement and, what is more important, usually the type of involvement. The x-ray is by no means infallible. There remains much that is not known, and there are lesions in which the ordinary film is of little value. Even films that are produced with the best of technique and visualize all the lesions present which are roentgen-demonstrable have to be interpreted. In general, a persistently negative chest x-ray fairly well eliminates pulmonary tuberculosis from consideration. It is inadvisable in any given patient to rule out pulmonary tuberculosis without a chest film. X-ray will often show lesions before there are any signs or symptoms and, in the presence of symptoms, will show the lesion in all cases to all practical purposes when the symptoms are due to pulmonary tuberculosis. Early tuberculosis that is active and clinically in need of therapy may exist with no signs or symptoms, these cases obviously are diagnosable only by x-ray.

In view of the preceding from the standpoint of the early diagnosis of pulmonary tuberculosis, the general practitioner with a full realization of the concepts outlined is faced with the problem of which patients he should advise to have their chests x-rayed. Whenever there is any suspicion of pulmonary tuberculosis a chest x-ray should be insisted upon. The presence of any symptom or sign that is unexplainable with any degree of certainty and may be found in pulmonary tuberculosis should excite suspicion. The following, when otherwise unaccountable, are examples: pulmonary hemorrhage or minor blood-spitting, tired feeling, weakness, loss of weight, afternoon fever, night sweats, cough, with or without sputum, which persists for more than six weeks, hoarseness, persistent rales over the upper third of the chest, and pleurisy with effusion, especially in young individuals. Pneumonia that cannot be typed or any atypical pneumonia regardless of the disappearance of clinical findings should excite suspicion. Rectal abscess in the absence of any explanation is suspicious, it is probably wise to x-ray the chest in every such rectal case. A physician who bears in mind the existence of pulmonary tuberculosis will also have in mind that "a cold may not

be a cold." Coughs that follow colds in the head are usually not serious, and all symptoms disappear in from two to six weeks. Afebrile ambulant cough of not more than two months' duration which has followed a cold in the head is usually evidence of a self-limiting subacute bronchitis and is not serious. Afebrile or subfebrile ambulant cough and pleural pain which are not preceded by an infection of the upper part of the respiratory tract are quite likely to be serious. An exception is pertussis, which is a primary bronchitis. Most patients who consult a physician because of ambulant coughs do so because they fear the possibility of serious disease, i.e., tuberculosis. In this group of ambulant afebrile coughs of short duration, tuberculosis is certainly the most common disease that is serious and threatening. The problem of its presence or absence can be solved quite simply by an x-ray film; also, there is no other way of solving it. The x-ray is not the whole answer to early diagnosis of pulmonary tuberculosis, but in all save a rare instance the x-ray will reveal a tuberculous lesion long before it produces symptoms, long before it produces the slightest physical signs, and long before the sputum is positive. This means that physical examinations, sputum examinations, temperature records, weight charts, sedimentation tests, blood counts, and everything else are of no value in ruling out the presence of pulmonary pathology and that in the vast majority of cases the diagnosis of early tuberculosis must be made and can be made by the x-ray.¹ The absence of significant findings in history, physical examination, and laboratory does not rule out tuberculosis, and their presence cannot diagnose tuberculosis but merely suggest its possibility or probability. The last mentioned, of course, excludes the finding of a positive sputum on the positive side and the finding of a persistently negative tuberculin test to lower dilutions on the negative side, which, however, could raise considerable controversy as to its acceptance as fact and would not, in the presented case, be ruling out other pulmonary pathology that may be present. Even though it is nontuberculous, it is

of equal importance that it be demonstrated if present.

Does this mean that everyone with complaints referable to the respiratory system should have an x-ray of the chest? There is only one possible reason for not proceeding on this principle and that is the expense that it would be to the patients. No one any longer dares to treat an injury to a bone or joint without an x-ray. The same should apply to diseases of the chest, for, whereas a small missed fracture may give slight deformity or disability, a missed early tuberculosis may give years of chronic illness and often death. Granted for the moment that it is not feasible economically, some way of distinguishing between those with ambulant coughs who are little likely, and those who are quite likely, to have tuberculosis or other serious lung disease may render useful service. The most common cause of ambulatory cough of short duration is subacute bronchitis secondary to infections of the upper part of the respiratory tract. With no contact history, no suspicious antecedent symptoms, an actually existent previous cold in the head, no hemoptysis, no pleural pain or persistent fever with the cough—one is probably safe in not x-raying. It is wise to give definite advice concerning symptoms and to demand a return. For example, "In all probability your cold has left you with a mild bronchitis that will go away in a short time. To be sure that nothing more serious is present an x-ray will be necessary. It is a good thing for everyone to have an x-ray of his chest occasionally, and you can either have one now or, if you wish, dispense with it and take it later only if the cough persists or some unexpected symptoms develop. Let me know if you develop fever, expectorate blood, or have any pain, and in any case come in to see me in two weeks."¹

X-ray is the *sine qua non* in diagnosis of diseases of the chest

THE CLINICAL SENSE

You may be skilled in the sciences, facile with chemical, physical, biologic, and many other techniques, you may know the physical manifestations of many diseases, you may contribute to the store of knowledge and be a medical scientist, but you will not be a physician until you have developed what has been called a clinical sense.

This is an acquired faculty based subtly but soundly on a broad knowledge, a retentive memory, a discriminating and orderly habit of mind, combined with an understanding of mankind.—Charles R. Austrian, M.D. *The Care of the Patient*, New England J Med 223 695 (October 31) 1940

PULMONARY TUBERCULOSIS IN NURSES

MILTON R. LOURIA, M.D., Brooklyn

IN RECENT years the subject of pulmonary tuberculosis in nurses has been accorded considerable attention by a number of investigators. Communications of interest and importance have been written by Heimbeck,¹ Geer,² Amberson and Ruggins,³ Ornstein and Ulmar,⁴ Ross,⁵ Jones,⁶ Myers, Diehl, and Lees,⁷ Soper and Amberson,⁸ and others. Most of these authors have concluded that the nursing of tuberculous patients entails a definite health hazard as demonstrated by a higher incidence of tuberculosis in nurses (particularly student nurses) than is encountered in a similar age and sex group not engaged in tuberculosis nursing.

It is not the purpose of this communication to review the literature on this subject. The present communication is designed to add further data gathered from a four-year study in a large general hospital with a tuberculosis service. An attempt will be made to analyze the development rate of clinical tuberculosis in the nursing group and to offer suggestions to decrease this rate.

Steps in the Process of Tuberculous Infection in Nurses

The careful study of nurses by means of frequent x-ray examinations and tuberculin tests has afforded an admirable opportunity for following the incidence rates of both primary infection and superinfection. This is clearly true among student nurses whose confinement to the hospital grounds during a course of training makes the chance of contact infection in the hospital small. Among the students in the course in training, the tuberculin-negative and the tuberculin-positive. One is thus able to obtain information about the relative frequency of clinical tuberculosis in these groups. Furthermore, valuable information is obtained in regard to the time interval in the development of the clinical infection, as evidenced by the appearance of a positive tuberculin test, and the time element between negative and positive x-ray films.

Observations have been recorded on the conversion of the tuberculin test from negative to positive in student nurses during their course in training. Heimbeck¹ found that

the student nurses at the General Hospital in Oslo, an institution with a bed capacity of 2,000 and a usual census of 300 to 400 cases of tuberculosis, were 48 per cent positive to tuberculin on admission and 100 per cent positive by the end of their three-year course. Myers, Diehl, and Lees⁷ reported that a group of student nurses were 35 per cent tuberculin-positive on admission and 95 per cent positive at the completion of their training course. The latter report is rendered more illuminating by contrasting the results of tuberculin testing in the School of Nursing with the testing of a comparable group of young women in the School of Education where there is no special exposure to tuberculosis. The latter group showed only a 4 per cent increase in positive reactors between the time of admission and the completion of the course.

Studies of the above type demonstrate clearly the first step in the process of infection—the development of the primary infection in previously uninfected nurses as a result of exposure to the tubercle bacillus. That such exposure is directly attributable to the occupational activity is also demonstrated by comparative figures with a group not similarly engaged.

The second step in the process of infection concerns the development of parenchymal reinfection tuberculosis. At this point we encounter two schools of thought: the one holds to the theory of endogenous reinfection, the other, to the theory of exogenous reinfection. It is not intended at this time to enter into a lengthy discussion of the merits of each of these schools of thought. However, it would seem pertinent to emphasize several points. In the first place, there is scant evidence to demonstrate that any significant number of cases of reinfection tuberculosis develop from the implantation of bacilli that have escaped from calcific foci in the lung or in the lymph nodes. Although viable bacilli have been demonstrated in such foci, histologic examination strongly suggests the difficulty of escape of bacilli from these areas. It has also been shown that a sortening of the primary focus may take place with actual progression of the disease from this region, but again it must be pointed out that such occurrences are admittedly rare. On the other hand, the evidence of a tuberculin-positive

be a cold." Coughs that follow colds in the head are usually not serious, and all symptoms disappear in from two to six weeks. Afebrile ambulant cough of not more than two months' duration which has followed a cold in the head is usually evidence of a self-limiting subacute bronchitis and is not serious. Afebrile or subfebrile ambulant cough and pleural pain which are not preceded by an infection of the upper part of the respiratory tract are quite likely to be serious. An exception is pertussis, which is a primary bronchitis. Most patients who consult a physician because of ambulant coughs do so because they fear the possibility of serious disease, i.e., tuberculosis. In this group of ambulant afebrile coughs of short duration, tuberculosis is certainly the most common disease that is serious and threatening. The problem of its presence or absence can be solved quite simply by an x-ray film, also, there is no other way of solving it. The x-ray is not the whole answer to early diagnosis of pulmonary tuberculosis, but in all save a rare instance the x-ray will reveal a tuberculous lesion long before it produces symptoms, long before it produces the slightest physical signs, and long before the sputum is positive. This means that physical examinations, sputum examinations, temperature records, weight charts, sedimentation tests, blood counts, and everything else are of no value in ruling out the presence of pulmonary pathology and that in the vast majority of cases the diagnosis of early tuberculosis must be made and can be made by the x-ray.¹ The absence of significant findings in history, physical examination, and laboratory does not rule out tuberculosis, and their presence cannot diagnose tuberculosis but merely suggest its possibility or probability. The last mentioned, of course, excludes the finding of a positive sputum on the positive side and the finding of a persistently negative tuberculin test to lower dilutions on the negative side, which, however, could raise considerable controversy as to its acceptance as fact and would not, in the presented case, be ruling out other pulmonary pathology that may be present. Even though it is nontuberculous, it is

of equal importance that it be demonstrated if present.

Does this mean that everyone with complaints referable to the respiratory system should have an x-ray of the chest? There is only one possible reason for not proceeding on this principle and that is the expense that it would be to the patients. No one any longer dares to treat an injury to a bone or joint without an x-ray. The same should apply to diseases of the chest, for, whereas a small missed fracture may give slight deformity or disability, a missed early tuberculosis may give years of chronic illness and often death. Granted for the moment that it is not feasible economically, some way of distinguishing between those with ambulant coughs who are little likely, and those who are quite likely, to have tuberculosis or other serious lung disease may render useful service. The most common cause of ambulatory cough of short duration is subacute bronchitis secondary to infections of the upper part of the respiratory tract. With no contact history, no suspicious antedating symptoms, an actually existent previous cold in the head, no hemoptysis, no pleural pain or persistent fever with the cough—one is probably safe in not x-raying. It is wise to give definite advice concerning symptoms and to demand a return. For example, "In all probability your cold has left you with a mild bronchitis that will go away in a short time. THE CLINICAL SENSE

You may be skilled in the sciences, facile with chemical, physical, biologic, and many other techniques, you may know the physical manifestations of many diseases, you may contribute to the store of knowledge and be a medical scientist, but you will not be a physician until you have developed what has been called a clinical sense.

This is an acquired faculty based subtly but soundly on a broad knowledge, a retentive memory, a discriminating and orderly habit of mind, combined with an understanding of mankind—Charles R. Austrian, M.D. *The Care of the Patient*, *New England J. Med.* 223: 695 (October 31) 1940

from the general population, it would seem of interest to disregard for the moment all cases among the student nurses except those whose disease was so advanced that detection under all circumstances would have been unavoidable. This would also exclude from consideration any minimal cases that might have developed into advanced types of tuberculosis. Of the 20 cases, 3 had cavities requiring collapse therapy and another had bilateral pleurisy with parenchymal involvement. On the basis of these cases alone, the development rate of tuberculosis is in excess of that found in a comparable group not engaged in an occupation with a definite and significant exposure to tubercle bacilli. This observation is in agreement with that noted by Jones² and others.

Pulmonary Tuberculosis in Graduate Nurses

In a group of graduate nurses there were 27 cases of clinical tuberculosis with 3 deaths during the four-year period. One of these nurses had an antecedent tuberculous node in the neck but had repeated negative chest films prior to the onset of her pulmonary lesion.

An analysis of the occupational history of the graduate nurses who contracted tuberculosis brings to light the important fact that of the 27 cases, 20 or 74 per cent were in active contact with tuberculous patients on the medical or tuberculosis wards. If we pause to consider that only 233 of the 950 graduate nurses were regularly employed on the medical and tuberculosis services, we find that 24.5 per cent of the graduate nursing group contributed 74 per cent of the cases of clinical tuberculosis. This means that the graduate nurse who works on wards where patients with tuberculosis are cared for has nine times as great a chance to contract the disease as the graduate nurse employed on wards where only occasional cases of tuberculosis are found.

The statistical data on the graduate nurse group have been compiled with as much accuracy as possible. However, it is desirable to make one modifying comment. Although it is a general practice to maintain graduate nurses on the same service year after year, a certain amount of shifting to different services must of necessity take place for administrative purposes. The figure mentioned above—that 24.5 per cent of the graduate nursing group contributed 74 per cent of the cases of clinical tuberculosis—must therefore be considered as having a certain incalculable

degree of error. However, I feel that the inherent degree of error in the figures is not of sufficient degree to offset the definite statistical implication which the figures carry.

The statistical data given above are of importance in consideration of the pathogenesis of reinfection tuberculosis. If such forms of tuberculosis were due to endogenous reinfection, one would expect the development rate of the disease to be the same in nurses, regardless of the services on which they were employed. Certainly the nurses on surgical or obstetric wards work just as hard as those on medical or tuberculosis services. And still the statistics leave no doubt that the actual exposure to exogenous infection is the all-important factor that accounts for the incidence rate of clinical tuberculosis.

Time Interval Between Admission to the Nursing School and Development of Tuberculosis

In each case of a student nurse who developed clinical tuberculous disease, the time interval for the development of the disease has been calculated. It seems hardly necessary to detail the figures for each case. The shortest period of time between admission to the nursing school and the discovery of clinical tuberculous disease was seven months, the longest period was thirty-one months. The average period of time in all 20 cases was nineteen and one-tenth months.

Time Interval Between Negative and Positive X-Rays

In the group of student nurses who showed evidence of tuberculous disease with positive x-ray findings, the interval between the last negative plate and the first positive plate has been computed. The reason for making this calculation is in order to obtain data on the time interval required to show the development of definite tuberculous disease on the x-ray film. It is obvious that the calculated interval is a great deal longer than the actual time needed for such changes. However, it suffices to indicate the maximum time that should be permitted to elapse between routine x-ray films in order to discover the disease at the earliest possible time.

The longest recorded interval was twelve months between a negative and positive plate, although it must have been an error of omission that another interval routine plate had not been taken since an attempt was made to take plates at intervals of six months. The average time in all cases between the last

vironment that has been proved capable of causing primary infection in almost all negative reactors must of necessity expose her to the same dose of bacilli that have been proved capable of causing primary infections. If reinfection tuberculosis is caused by the implantation of bacilli in previously sensitized tissue, why is it necessary to invoke the problematic escape of bacilli from primary or old fibrotic foci when we have ample evidence of the same organisms entering the respiratory system from without? The weight of evidence would certainly seem to favor the school of thought that considers most cases of reinfection pulmonary tuberculosis as being caused by the aerogenous, exogenous implantation of bacilli.

Material for Study

The Kings County Hospital is a general hospital with a bed capacity of about 3,000. The institution cares for all types of cases except the communicable diseases, such as diphtheria and scarlet fever. A special tuberculosis service accommodates approximately 200 patients. However, patients with pulmonary tuberculosis are also admitted to the medical wards from which they are transferred to the tuberculosis service when vacancies occur. During recent months the census of patients with pulmonary tuberculosis on the general medical wards has varied from 80 to 120.

The Kings County Hospital conducts a training school for nurses. The applicants are given a complete physical examination including x-ray of the chest before admission. Mantoux testing is done at the time of admission, negative reactors are retested at regular intervals. No applicant with evidence of a pulmonary lesion is admitted to the school, although the finding of small fibrotic strands has not in the past necessarily caused the rejection of the applicant. The course in training includes one month on the tuberculosis wards. Since June, 1938, this has been omitted in an attempt to decrease the number of cases of tuberculosis among the student nurses. Student nurses have had x-ray examinations of the chest at six-month intervals, since February, 1938, the interval has been reduced to four months.

Approximately 950 graduate nurses are employed at the hospital. The nurses have a complete physical examination and an x-ray of the chest before admission. X-ray of the chest is repeated at yearly intervals except in those cases where a suspicion of illness

necessitates more frequent examination. Nurses assigned to the tuberculosis division are required to have an x-ray of the chest at intervals of three months.

The following table indicates the number of students in each entering class from September, 1935, until September, 1938, and shows the number of cases of pulmonary tuberculosis that have developed in each group.

Entering Class	Number of Students	Number of Cases of Tuberculosis
September, 1935	29	5
February, 1936	23	1
September, 1936	46	3
February, 1937	45	8
September, 1937	57	2
February, 1938	43	0
September, 1938	77	1
	<hr/> 320	<hr/> 20

This table indicates that 6.25 per cent of the student nurses showed evidence of clinical pulmonary tuberculosis during a four-year observation period, with an average observation period of two years. This figure is almost identical with that reported by Ross⁶ of a 6 per cent occurrence among 800 nurses in training in Manitoba during a four-year period.

A critical analysis of these figures justifies the statement that it is unfair to compare them as they stand with statistics gathered from the general population. The reason for this point of view is obvious. It has been repeatedly observed that the cases of pulmonary tuberculosis reported to the health authorities are predominantly of the moderately and far-advanced groups. Minimal cases of tuberculosis in larger numbers are usually disclosed only by systematic case-finding projects. Among the 20 cases of pulmonary tuberculosis in the student nurse group, many had lesions so minimal and symptoms so scant that the diagnosis may well have escaped detection had these young women been members of the general population rather than a group under thorough and frequent observation. Some cases could undoubtedly have gone through the phase of activity and healing while the individuals continued their usual duties. That such events do take place in the general population is well recognized. On the other hand, it would also seem logical to assume that some of the minimal and relatively asymptomatic cases might have developed into advanced cases if the progress of the disease had not been checked during the early stages.

In order to arrive at figures that can be more easily compared with those compiled

sex group in the general population. Let us further assume that the statistical data thus gathered would show exactly the same percentage of cases of tuberculosis in both groups. Does that mean that the risk of contracting tuberculosis is the same in both groups? Decidedly not. In the first place the nurses comprise a carefully selected group from which all cases of tuberculosis had been previously excluded by thorough examination. Furthermore, the student nurses should theoretically have the low incidence of tuberculosis found in the high-income group rather than the higher incidence of the average-income group. It is well recognized that tuberculosis is less prevalent in the group whose income permits individual bedrooms and adequate diet. Student nurses are housed in individual rooms and receive a diet calculated and prepared under the supervision of trained dietitians. Although their surroundings may not have the elegance of the homes of the wealthy or their food may not possess Epicurean qualities, it would seem that the student nurses are cared for in housing and nutrition according to theoretic standards that should result in a minimal incidence of tuberculosis. These nurses are almost completely protected from familial or household contacts with tuberculous disease which account for so many cases in the general population. If, in the face of these conditions, the student nurses show even the same incidence of tuberculosis that is found in a similar age and sex group in the general population, it would appear logical that the professional activities are causative and that the actual incidence of tuberculosis is distinctly higher than the theoretic anticipated rate under similar conditions of living without contact with tuberculous patients.

Similarly, in the graduate nursing group statistical data require fair interpretation. In the first place we must realize that the graduate nursing group is the result of numerous health screenings. As a student nurse she was denied admission to the school of nursing if she was found to be suffering from tuberculosis. During her student days she is under constant medical supervision. If tuberculosis develops, it is likely that she will not complete her training course. Acceptance as a graduate nurse again calls for a complete physical examination. If tuberculosis is found, she will not be employed by the hospital. It would thus appear that the graduate nurse is one who has successfully passed a series of health screenings. If some

people have greater susceptibility to the contraction of tuberculosis than others, it would seem likely that graduate nurses fall into the more resistant group. If, in face of these facts, a case-finding survey in the graduate nurse group shows an incidence of tuberculous disease equal to that among a similar age and sex group in the general population that has not been subjected to rigorous and repeated health screenings, one would be justified in concluding that the nursing activities caused a higher than expected tuberculosis incidence.

Methods for Decreasing the Incidence Rate of Pulmonary Tuberculosis Among Nurses

If the exogenous theory of reinfection is accepted—and I feel strongly that the available evidence substantiates this theory—then the logical approach to minimizing the development of tuberculosis among nurses lies in the rigid application of nursing technic designed to prevent access of the tubercle bacilli to the nurses. This is by no means a new concept. The introduction of such measures has apparently led to a marked reduction in the incidence of the disease at the Anker Hospital in St. Paul, as reported by Geer.² Soper and Amberson³ reported a communication from Stiehm to the effect that the introduction of strict isolation technic at the Wisconsin General Hospital has resulted, during the past five years, in the absence of any case of tuberculosis among the pupil nurses.

It is quite unnecessary to go into minute details concerning nursing technic. However, a few points deserve special mention. All patients should be masked during examination by physicians. This is not only for the protection of the physician but also of the nurse who is in attendance. All patients should be masked while the nurse is giving them baths or similar close attention.

Nurses should wear caps, gowns, and masks while in close contact with patients as in bathing or feeding them. These protective articles should be discarded for sterilization after each period of the day devoted to these specific nursing duties. Frequent scrubbing of the hands is of great importance.

Hospital regulations must pay particular attention to the technic of collecting and disposing of sputum cups. The sputum cup that is permitted to become full is a potent source of distributing bacilli over bedside tables and bedcoverings. The noncooperative patient (only too frequently found in the

negative and the first positive film was five months. The most striking disclosure was that the shortest interval was fourteen days. From these figures one can draw only a single conclusion: that the arbitrarily accepted figure of six months for routine x-ray studies of nurses exposed to tuberculous infections is too long. A three-month period would seem more desirable and would certainly seem to justify the additional expense and trouble involved.

It would also seem worthy of mention that one of the patients with caseous pneumonic disease requiring pneumothorax therapy had a negative x-ray only three months before clinical evidence of the disease was discovered. It would seem that the pathologic character and extent of tuberculous disease is dependent in a large measure upon the intensity and frequency of exposure. This would serve as an additional reason for the taking of x-rays of nurses exposed to the disease at more frequent intervals.

The Degree of Immunity Conferred by a Positive Tuberculin Reaction

Many workers in the field of tuberculosis have felt that a positive tuberculin reaction confers a relative immunity against exogenous reinfection. Heimbeck in Norway has used bacillus Calmette Guérin to vaccinate the tuberculin-negative nurses in order to confer a degree of immunity. Of the student nurses who were studied in the present survey, 47 per cent were tuberculin-negative, and 53 per cent were positive on admission. This figure agrees fairly closely with that of Heimbeck in Oslo, who found that 48 per cent were positive on admission, and also with that of Badger and Spink⁹ of the Boston City Hospital, who reported 57.1 per cent positive on admission.

In the present series of student nurses only 26 per cent of the clinical cases of tuberculosis came from the tuberculin-positive group, and 74 per cent from the tuberculin-negative group. This makes the chances of a student nurse with a negative tuberculin test on admission contracting tuberculosis three times as great as that of a tuberculin-positive student. This ratio is considerably lower than that of Heimbeck, who found a relative proportion of about 8 to 1 in the tuberculin-negative as opposed to the tuberculin-positive group.

The statistical figures from the present study require a word of comment. Many of the nurses were tested only with 1 to 1,000

O.T. At a later date those reacting negatively with 1 to 1,000 were retested with 1 to 100, subsequently P.P.D. was employed. Hence, it is possible that the disparity in this series between the ratios of infection in the tuberculin-negative and the tuberculin-positive is not as great as would appear from the calculated figures. It would seem likely that some of the nurses who did not react to the 1 to 1,000 O.T. might have reacted positively to a stronger dilution at the time of the first testing.

Influence of Early Background on Development of Tuberculosis in Student Nurses

Inquiry was made regarding the place of birth and locale in which the student nurses lived before coming to the hospital. An arbitrary line was drawn between towns above 10,000 in population and those with a smaller population. Of the 20 students who showed clinical evidence of tuberculosis, 9 came from towns with a population under 10,000 and 11 came from towns with a population over 10,000. Among the entire student body studied, about one-third came from communities with a population under 10,000.

I do not believe that this single series is large enough to base any conclusions on the relative rate of development of pulmonary tuberculosis in student nurses coming from small towns or rural communities in contrast with those who have grown up in more crowded localities. However, the use of these figures in conjunction with those gathered by other investigators may be of value in future studies.

Family History of Tuberculosis

Only 1 case among the student nurses had a family history of tuberculosis. However, it was found that the contact was slight. This patient also had two negative x-ray plates before the positive plate that showed evidence of disease. It would thus appear that a family history of tuberculosis played no role in the development of tuberculosis among the student nurses studied in this survey.

A General Critique of Tuberculosis Statistics in Nursing Groups

A note of caution must be introduced in the evaluation of tuberculosis statistics in a selected group such as nurses. Let us assume that a case-finding project is carried out in a nursing group and that a similar project is simultaneously concluded in a comparable age and

Therapeutics

CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the September 1 issue and will concern "General Management of a Seriously Ill Patient."

The Use of Human Convalescent Serum

DR EUGENE F DuBOIS This conference will deal chiefly with the use of human convalescent serum, and we are fortunate in having with us Dr William Thalheimer, director of the Manhattan Convalescent Serum Laboratory. Dr Thalheimer, will you lead off?

DR WILLIAM THALHEIMER In the brief period allotted to me, one can only hope to introduce this large subject and trust to the discussion to bring out some of the details.

It might be well to begin by stating some general rules for the use of therapeutic serums in all infectious diseases. These rules have grown out of the combined experience of many.

Any therapeutic serum should be given in a sufficiently large dose at one time as early as possible in the disease. If this is done, not infrequently further injections are unnecessary. In the case of critically ill patients, the intravenous administration of serum is the method of choice. By that method of administration the serum is immediately distributed throughout the body, and the therapeutic effects come on without the delay due to absorption. It is probably not generally known that it requires from sixteen to eighteen hours for maximum absorption of a serum after intramuscular injection and that the titer of the serum in the circulating blood at the end of that time is only half as high as after a similar dose of serum injected intravenously. Also, after the intravenous injection the titer is at its maximum immediately instead of sixteen or eighteen hours later. Obviously, the intravenous route of injecting animal therapeutic serums is not used often because there is a definite risk of severe reactions, even of anaphylactic shock.

Serum is rapidly absorbed after intraperitoneal injection. This is a safe route for administering serum. This method should be the one of second choice in treating severely ill patients but, strangely, these facts are not generally realized. Platou in 1923, working

at the Willard Parker Hospital, demonstrated that diphtheria antitoxin is extremely rapidly absorbed after intraperitoneal injection and that a high titer of the antitoxin is present in the circulating blood within an hour or two. Banks, in England, found the same to be true of scarlet fever antitoxin. Banks also found that the systemic reaction is not any more severe after intraperitoneal injection of scarlet fever antitoxin than after the intramuscular injection, and much less than after the intravenous injection. Banks uses the intraperitoneal route routinely for scarlet fever antitoxin in the treatment of those patients sufficiently ill to require antitoxin treatment. One of the possible reasons for the fact that this method of administration is not more generally used is the belief that there is risk of injuring the intestines or of causing peritonitis. But it seems to me that there is sufficient experience from the practice of peritoneal puncture for diagnostic purposes and also from the work of Banks and others to indicate that this method of administration should be considered more seriously than it usually is.

The opinion is quite general that serum injected intramuscularly stays in the circulation longer than when injected intravenously. However, the number of antibodies in the circulation decreases from its peak just as rapidly after the intramuscular injection as after the intravenous injection. In cases in which one cannot administer a serum intravenously with safety, one can maintain a high titer of antitoxin in the blood by repeated intramuscular injections.

The ideal therapeutic serum, I think, can be described briefly as one that has high therapeutic potency, that is concentrated to small volume, and that is safe for intravenous injection. Unfortunately, this ideal has not yet been reached with animal serums, although there can be no question about the fact that

large wards of city institutions) must be isolated, preferably in a separate room or a small ward. For these patients, strict isolation technic should be enforced. Constant observation of patients' habits, particularly coughing without covering the mouth, is necessary to minimize the spread of bacilli.

In addition to points in nursing technic and hospital administration such as have been mentioned above, the following recommendations may well contribute to a decrease in the development of tuberculosis among nurses.

1 Nurses on active tuberculosis service should not be permitted to spend more than four hours a day on the wards. The remainder of the working day should be allotted to duties that do not entail contact with tuberculous patients.

2 Nurses on active tuberculosis service should have frequent vacations.

3 These nurses should have routine chest x-rays at intervals not exceeding three months.

4 As far as possible, tuberculosis services should be divided into positive and negative wards, the nurses' schedules should be so adjusted that one group is not constantly in attendance on the positive wards.

Summary and Conclusions

1. A study has been presented of pulmonary tuberculosis developing among student nurses and graduate nurses in a large general hospital with an average census of approximately 300 tuberculous patients.

2. A somewhat higher occurrence of tuber-

culosis was found among student nurses that were tuberculin-negative on admission than in the tuberculin-positive group.

3. A higher incidence of tuberculosis was found in student nurses coming from small towns and rural areas than in the group coming from larger towns.

4. Among the graduate nurses, it was found that the majority of the cases were derived from a minority of the group whose duties brought them into frequent contact with active cases of tuberculosis.

5. This study lends support to the theory that the exogenous route of infection rather than endogenous infection from an old primary complex accounts for most cases of clinical tuberculosis in nurses.

6. Recommendations have been given for reducing the occurrence rate of tuberculosis among nurses.

"LEAVE 'EM WHERE THEY LIE"

(Prepared by the Fracture Committee, Texas State Medical Association, sponsored by Texas State Highway Department and Texas Public Safety Commission.)

Preamble

Series of Instructions on First Aid Following Injuries on the Highway—Leave 'Em Where They Lie

You, Mr. John Public, have, through the press and other sources of general information, been told many things and been taught much about public health, about contagious diseases and their prevention, about tuberculosis and cancer.

You have learned much in the prevention of disease, in how reasonably to take care of yourself and your family when trouble threatens or arrives.

You have been taught that wounds may become infected and to go to your doctor early, you have been taught that a broken bone must be set, but you have not been taught what to do and why in the case of injury and emergency

on the highways, where there is no one to whom to turn and you only have your own knowledge and ability to take care of such emergencies yourself.

The series of articles on the subject of highway accidents, describing each one in turn and telling you in each instance what and what not to do, is being published for your information, only to help you help yourself or someone else—your wife, your mother, your child, your neighbor—in such an emergency when the difference between saving life or limb depends upon doing the proper thing at the right time. A single act, wisely done, is better than a hundred acts hurriedly done without reason.

Why are you told to "leave 'em lie?"

Because unless you have been taught what to do, you will do much more harm than good, because excitement, hurry, improper handling, which often complicates matters seriously, and rushing to a hospital or doctor increases shock tremendously and costs many lives.

Have the doctor or ambulance come to you and save lives —*Texas State Journal of Medicine*

"LEAVE 'EM WHERE THEY LIE"

(Prepared by the Fracture Committee, Texas State Medical Association, sponsored by Texas State Highway Department and Texas Public Safety Commission.)

Preamble

Series of Instructions on First Aid Following Injuries on the Highway—Leave 'Em Where They Lie

You, Mr. John Public, have, through the press and other sources of general information, been told many things and been taught much about public health, about contagious diseases and their prevention, about tuberculosis and cancer.

You have learned much in the prevention of disease, in how reasonably to take care of yourself and your family when trouble threatens or arrives.

You have been taught that wounds may become infected and to go to your doctor early, you have been taught that a broken bone must be set, but you have not been taught what to do and why in the case of injury and emergency

on the highways, where there is no one to whom to turn and you only have your own knowledge and ability to take care of such emergencies yourself.

The series of articles on the subject of highway accidents, describing each one in turn and telling you in each instance what and what not to do, is being published for your information, only to help you help yourself or someone else—your wife, your mother, your child, your neighbor—in such an emergency when the difference between saving life or limb depends upon doing the proper thing at the right time. A single act, wisely done, is better than a hundred acts hurriedly done without reason.

Why are you told to "leave 'em lie?"

Because unless you have been taught what to do, you will do much more harm than good, because excitement, hurry, improper handling, which often complicates matters seriously, and rushing to a hospital or doctor increases shock tremendously and costs many lives.

Have the doctor or ambulance come to you and save lives —*Texas State Journal of Medicine*

patients during convalescence from these diseases, at intervals of from two or three weeks and for a period of four months after the onset of the illness. The serum which results is processed with sterile technic and is proved to be sterile at every stage. Only those with a negative Kahn and Wassermann are used. They are finally pooled, thirty or forty in a pool. Merthiolate is added to the dilution of 1 to 10,000, and the final preparation after filtration through a Berkefeld is placed in vials, and the proper number of vials as required by the United States Public Health Service are tested for sterility. The sterility test is held for seven days. Also, some serum is injected into mice and guinea pigs for animal toxicity tests. Only after sterility and toxicity tests have proved negative is the serum finally released for use.

We have available two specific serums for scarlet fever. Their therapeutic and prophylactic value is established. One is human convalescent serum and the other is antitoxin (animal). About 10 or 15 per cent of the children exposed to scarlet fever will contract this disease. Our records indicate that when children receive 20 cc of convalescent fever serum intramuscularly only 1 or 2 per cent will develop scarlet fever, and those that do develop the disease have, in our experience, developed it in a mild form, in some it is even incomplete, with sore throat and cervical adenitis but without a rash or other signs. Therefore, one can say that about 80 or 85 per cent of the children whom one expects to develop scarlet fever escape it when they receive convalescent serum prophylactically. So much for prophylaxis.

The curative results with the intravenous injection of convalescent human serum are quite dramatic. The following dose should be used in children who are acutely ill with scarlet fever—namely, those with high temperatures, with rash and marked toxicity—in the very early stages of this disease, up to about thirty-six hours after onset 20 cc intravenously for children up to the age of 5, 40 cc for those from 5 to 10, 60 cc for those from 10 to 15, and 80 to 100 cc for large adolescents or adults.

In from 75 to 80 per cent of those treated, the disease is aborted. In from twelve to eighteen hours one frequently sees an extremely ill and toxic child transformed into a convalescent one. Within this period the temperature falls by an average of 3 to 4 degrees, often the rash begins to disappear and the marked toxicity subsides. Some-

times there is a slight rise of temperature during the second twenty-four hours, after which it usually returns to normal and stays there. If treatment is delayed for three or four days after the onset of the illness or if, even in the early stages, complications have already appeared, then the results are not so rapid and not so dramatic, but they are still worthwhile. Under these circumstances several injections of serum might have to be given, whereas in the children treated early, as just described, usually one injection is sufficient. The percentage of complications in the treated cases is reduced to one-third of that expected, and complications are usually much less severe. After intramuscular injection the action is not quite so rapid and the serum is not so effective. Similar results can be obtained with the use of scarlet fever antitoxin. I have had no personal experience with it, but my belief is, from reports which have come to me, that the results are obtained somewhat more slowly since this material is administered intramuscularly. I know of no reports of antitoxin being administered intravenously.

We may now pass on rapidly to measles convalescent serum. Its use is confined almost entirely to prophylaxis. With this serum administered intramuscularly not later than the seventh day after exposure to measles, 49 per cent of the children escape measles. Only 0.7 per cent develop the usual form of the disease, and the rest develop a modified form of measles which is often so slight that it is difficult to make the diagnosis unless one is familiar with the modified disease. Modified measles is somewhat different in appearance from mild unmodified measles. Dr. Stimson can tell you more about that. In our experience, therefore, 99.3 per cent of the children who receive a proper dose of measles convalescent serum not later than the seventh day after their exposure will either not develop measles at all or will develop modified measles. Modified measles is a much milder disease. In oversimplifying that, one may consider it a one-day mild, febrile disease rather than the usual three- or four-day disease. Modified measles confers a considerable degree of permanent active immunity to measles. However, from the few instances that we happen to know about, I think we can state—and this might have to be corrected by later experience—that a child who develops a barely detectable modified measles cannot be considered completely resistant to measles on subsequent exposures. Dr. Stimson might tell of 1 case of

many of the serums are now safer than they used to be because of the improved methods of refining

Before injecting animal serums intravenously one should test the patient for sensitivity, and the test should be made with normal serum of the same animal species and not with the therapeutic serum

There are several efficient human serums that can be administered intravenously with safety, in large amounts, and repeatedly

In recent years I have been interested in human therapeutic and prophylactic serums, particularly measles and scarlet fever convalescent serums. I may relate briefly some of the results that we have obtained and which have been reported to us by many physicians who have used these serums. These serums can be injected intravenously with safety, because one is not introducing foreign protein. It is introducing human proteins into humans. One must immediately state, however, that the serums have to be carefully prepared, otherwise reactions would result such as occur in from 3 to 10 per cent of compatible blood transfusions. In 1 or even 2 per cent of the cases a febrile, or possibly a chill, reaction takes place after the intravenous injection even of properly prepared human serum, but the incidence of these is much smaller than that of reactions following compatible blood transfusions, and they are not more frequent than reactions after the intravenous injection of saline or glucose solutions

The question always comes up as to whether the incompatible isoagglutinins that are present in pooled serum might not be dangerous to inject intravenously. Categorically, one can say no

The rules that apply to the intravenous injections of incompatible cells do not apply to incompatible agglutinins. Of course, it is most dangerous to inject incompatible cells intravenously. However, upon the basis of a large experience of many people and also of some investigations of our own, we can say that in pooled serum that has been prepared from blood obtained from individuals belonging to the various blood groups the titer of agglutinins is likely to be relatively low. This is so because there is dissolved agglutininogen in serum and some of the agglutinin is absorbed by it in pooling, also, the serum is immediately diluted in the entire circulating blood of the individual who receives it. Furthermore, the results of some investigations that we have carried out with the aid of Dr

Klein and others at the Willard Parker Hospital and elsewhere show that incompatible agglutinins, injected intravenously, disappear immediately from the circulating blood. We used children with scarlet fever. We injected serums containing incompatible agglutinins. We secured a sample of blood from the patient immediately before the injection and another from the other arm, using a different sterile syringe, immediately after the injection. We never found any agglutination of the patient's cells because of the injected incompatible agglutinins. What is more, we failed to find these incompatible agglutinins, although only two or three minutes had elapsed since their injection. They had disappeared.

We carried out the same type of experiment in test tubes in which we made similar dilutions in heparinized blood. We found that one can detect agglutination of cells when the serum containing incompatible agglutinins is diluted as high as 1:160. We were also able to detect some unabsorbed agglutinins.

The incompatible pooled human serum has been so administered as to result in a dilution in the patient's circulating plasma, at times, of not more than 1:14 and still all of the agglutinins disappeared immediately. Since one does not find the free agglutinins in the circulating blood, we were led to believe that the absence of reactions is not due only to the dilution of the incompatible agglutinins. The agglutinins are not absorbed only by the cells circulating in the patient's blood. It must be that the final removal of the agglutinins is accomplished by fixed tissue cells. We know that fixed tissue cells have specific agglutinogens and will absorb agglutinins.

We have also injected into patients serum with incompatible agglutinins, concentrated to one-third of its volume. In these individuals the amount was the equivalent of 300 to 400 cc of isotonic pooled serum for adults weighing about 150 pounds. No reactions resulted, the agglutinins disappeared completely.

As you all probably know, the British are making extensive use of isotonic plasma or serum by intravenous injection in the treatment of patients in shock. They almost always inject from 1,000 to 2,000 cc. They have reported no reactions, although the pooled serum has undoubtedly contained agglutinins incompatible for some patients.

Briefly, scarlet fever and measles convalescent serum is prepared by drawing blood from

hospitalization among 4,000,000 soldiers. Next to that were the venereal diseases, particularly gonorrhea, which cost 3,900,000 days, but mumps with its 3,800,000 days was a close second, and measles with 1,800,000 days was about half as much.

It is of interest to note that in the Army records there were 17,000 cases of German measles with 211,000 days lost and 82 deaths reported. Whereat one crosses one's fingers skeptically, and if you look a little further you find that most of these cases of German measles and all of the deaths were reported from Army camps where relatively little scarlet fever was reported. They probably did not know the difference. Altogether scarlet fever cost only 500,000 days or 354 deaths in soldiers. Typhoid fever and smallpox, the two diseases which cost the Army most and were most prevalent in previous wars were negligible factors in the first World War. Smallpox caused altogether only 850 cases and 14 deaths, which is remarkable when you consider that about 40,000 of our troops in the Philippines were exposed to an epidemic that caused 100,000 deaths in the civilian population there during the period of the World War.

Doctors ought to be able to do something to prevent this tremendous loss of time and considerable loss of life for which the contagious diseases are responsible.

Theoretically, we ought to be able to prevent measles and mumps. Of course, scarlet fever and diphtheria are preventable, but scarlet fever did not cost much time loss, and diphtheria cost even less.

Measles and mumps cost the Army a tremendous amount of time, and measles occurred particularly in those troops that came from the rural districts. The troops that came from the cities had little measles, and it would seem that blood could be taken from the city troops, pooled, and used in the camps that get their troops from the rural districts. The same might be done for mumps.

There are now a number of reports of summer camps in which mumps appeared and the camp doctors took energetic measures, obtaining convalescent serum from somewhere. Perhaps, some of them got it from you, Dr Thalheimer?

DR. THALHEIMER: Yes.

DR. STIMSON: They apparently had good results. It would seem worthwhile to give adults who are exposed to mumps fairly large injections, 20 to 30 cc if one can get it.

Appropos of obtaining measles serum, it has been shown that blood taken from a person

who is incubating measles, especially in the last half of the incubation period, is infectious. It can transmit measles and, of the thousands of people who are donating blood to England for pools of serum for the treatment of shock, it is to be hoped that none are incubating measles. There is no way of testing those who are incubating measles until after they have come down with measles. Theoretically, that might cause trouble but practically it probably will not because each blood, as I understand it, is pooled with thirty or forty other bloods and most of it is so-called adult measles serum—that is, it is blood from adults who have had measles in childhood—and presumably there are enough antibodies in pooled serum to neutralize any virus that might be in a single specimen. However, it is a point worth considering.

The infectious or contagious diseases are roughly divisible into two groups: those due to bacteria and those due to viruses.

In those that are due to bacteria, serums are valuable both for prevention and for treatment.

In those due to viruses, serums theoretically are valuable for prevention in those cases that begin as a blood-borne infection. If the virus gets into the blood first and is present in the blood for an appreciable length of time, the administration of serum should be of prophylactic value. It is so in measles and it probably is so in mumps, but it has not yet been proved so in chickenpox and smallpox both of which begin certainly as blood-borne virus infections—that is, they begin as constitutional infections. This may be because we have not given them enough serum. If we gave these people 100 to 200 cc of convalescent serum instead of 20 cc, it might be effective. It has not been tried in smallpox because we have another preventive that is more effective, vaccination. In the virus diseases where the virus travels along nerves, theoretically, the administration of serum cannot be effective—for instance, in poliomyelitis.

The virus is cell bound almost at once and, therefore, the administration of serum is not likely to be helpful in treatment. That proves to be the case with the one possible exception of measles, as Dr Thalheimer said, but in that case the serum has to be given exceptionally early, almost before the Koplik spots appear. One can get a hint of the presence of measles even earlier if one watches the eyes. The caruncle in the inner corner and the plica semilunaris are apt to be swollen and red before Koplik's spots appear.

his in which a little child developed a mild measles after convalescent serum, the following year the child again developed measles, and this time it was also a modified measles. It would appear that if the modified measles is not too much modified, that if it remains severe enough so that an appreciable rash develops, then the child can be considered quite resistant to measles at subsequent exposures.

It is generally assumed that, by the time the rash appears, the child with measles has already been infectious for four days. At this time the child in contact with the patient in its home may be considered to have been exposed for four days. This bears on dosage. When we have calls for serum under these circumstances we advise the dosage on the basis of four days' exposure. We are not very certain of the dosage necessary in the various age groups and kinds of exposure. We have been investigating this for three years and we are still at it. We hope to have enough results to publish by the end of this year. We know the dosages necessary for protecting children who have been exposed to another child with measles in their own home in the tenement house type of residence. There you have the severest test, I believe, of the prophylactic efficacy of serum. The dosage is larger than we thought previously. At present we are recommending that no infant, even up to the age of 1 year, shall receive less than 5 cc. of serum intramuscularly. From 1 year on up to 10, they should receive 10 cc., and children over 10 should receive 15 or 20 cc.

The fact that one cannot secure 100 per cent protection with any material that I know of is of especial importance for institutions, hospitals for sick children, and orphan asylums. There will always be some secondary cases of modified measles. From a public health point of view, the fact that the exposed child may develop a mild measles, with partial permanent resistance to measles after the serum, is fortunate. Even in institutions the modified measles is better than complete protection, because if it is complete there will come the time, beginning about ten days after immunization, when the child is again susceptible. In private practice we recommend the effort to immunize completely against measles in all children up to the age of 1, because in that age group the mortality from measles is highest due to complications, particularly pneumonia. It is probably not generally realized that the mortality rate of measles and its complications in individuals up to 1 year is 8 per cent and that the group

mortality rate for children up to the age of 3 is probably 4 or 5 per cent.

Can anything be accomplished therapeutically once the signs of measles have begun to manifest themselves? There are two phases in the period of active measles: one is the Koplik spot, pre-eruptive stage, the other, the eruptive stage and that which follows. Work carried out by Drs. Kohn, Klein, and Schwarz at the Willard Parker Hospital on a group of about 30 children who were given large intravenous doses of convalescent measles serum, 40 to 50 cc. in the Koplik spot, pre-eruptive stage, showed that in 85 per cent of these children the disease was influenced by the serum and, instead of its developing into the full-blown unmodified disease, it developed into one-day mild measles. This method is not recommended for general application but in special cases, such as a child ill with pneumonia or poliomyelitis, or one who has recently recovered from diphtheria. So far as we can make out, although many studies in the literature report to the contrary, once the rash has developed, measles convalescent serum is not able to influence favorably the course of the disease.

In children from 3 to 5 years of age and older who are healthy and whose home conditions are good we believe we are doing the best by the child and by the community by attempting merely to modify the disease and confer active immunity in the child rather than attempt to protect it completely.

Dr. DuBois. We will now ask Dr. Stimson to continue the discussion.

Dr. PHILIP M. STIMSON. Many of you here are liable to see sick soldiers during the next two or three years, and I took the occasion to look up the figures of the contagious diseases in the United States Army in the last war. It is of interest to note, for instance, that there was enough mumps in the Army to cause a loss of time equivalent to putting a division of 27,000 men out of duty for nearly five months. This seems incredible, but in actual figures that was 230,000 cases, with a loss of 3,800,000 days. In two large Army camps over one-fifth of the men contracted mumps. Similarly with measles, there were twice as many cases of measles as there were men killed in the field of battle, the figures being 98,000 cases of measles with 2,000 deaths from the 6,000 cases of pneumonia. As a matter of fact, the infections of the upper part of the respiratory tract were the principal illnesses that caused loss of time, there being over 1,000,000 cases that required

members of the family can be used for prophylaxis of measles providing one uses enough and providing one is certain that they have previously had measles and that there is no risk of transmitting syphilis or malaria. Four cubic centimeters of such serum should be injected for each 1 cc of convalescent measles serum. The equivalent of a 10-cc dose of convalescent serum, which we recommend for children between the ages of 1 and 10, is 40 cc, a rather large amount to inject intramuscularly. Since blood is made up of only 50 to 60 per cent of plasma, the amount of whole blood injected should be twice that of the amount of serum just given.

STUDENT I should like to ask two questions. What is the variation in potency among different lots of convalescent serum, because in the final analysis that might determine the dosage? Has the use of hyperimmunized individuals such as donors been considered—that is, immune individuals whose antibody content is increased by injections of measles virus?

DR. THALHIMER There is no laboratory method of standardizing measles convalescent serum. It would require a standard virus and a standard animal to which one could give measles. The only animal one can give measles to is the monkey and then only with considerable difficulty. Therefore, the only method of evaluating the dosage in measles is the empirical one, observations in humans.

With scarlet fever we can determine the amount of scarlet fever antitoxin in human convalescent serum—that is, antitoxin for the erythrogenic toxin. There are only about 10 units of antitoxin per cubic centimeter of human convalescent serum. The number of units of antitoxin in the usual dose of convalescent serum is small compared to that in the dose of animal antitoxin. In human convalescent serum there are also bactericidal substances against hemolytic streptococci, and other immune bodies as well, which are not present in scarlet fever antitoxin. The fact that we obtain just as good, if not better, clinical results with the dosage of convalescent serum we use, even with its small content of antitoxin, we believe, demonstrates that these other antibodies play a part in the therapeutic effect and that the amount of antitoxin which is needed to control toxemia in scarlet fever patients is not so large as has been previously thought.

I think one might question the term "hyperimmunization." There can be a higher or lower level of immunization. But I am not

sure whether one is justified in referring to any one as hyperimmunized. In the way in which the term is used, to hyperimmunize measles' donors, one would have to have plenty of measles virus in a form that would not expose the subject to danger—namely, attenuated or killed virus. Few people, I believe, have been able to cultivate measles virus. Plotz at the Pasteur Institute in Paris, then Rake, and one or two others have succeeded. I think Dr. Goodpasture has also been able to grow it.

DR. DUBOIS I should like to ask a question that is of considerable military importance at the present. What is the status of tetanus toxoid? Dr. Thalheimer, will you comment on that? Do you advise its general use in the Army?

DR. THALHIMER It seems to me, from the evidence that has been accumulated and is being added to with great rapidity, that it is of great importance for general use. Dr. Donald Fraser, of Toronto, who was in New York a few days ago, stated that he feels the same way about it. All the Canadian soldiers are being immunized with it, as well as many people in the civilian population. There was a note in the *Lancet* by Perry, who compared the occurrence of tetanus in this war with that in the last war. In the last war it was something like 8 per one thousand and this time it is a fraction of 1 per cent. He also stated that no wounded soldier known to have received tetanus toxoid had yet developed tetanus in the present war, but he said also in all fairness that some of those had also received tetanus antitoxin after their recent injuries.

DR. DUBOIS I am sorry we have no further time for discussion.

Summary

DR. HARRY GOLD This discussion has dealt chiefly with the use of human convalescent serum in the control of various infectious diseases—namely, measles, scarlet fever, whooping cough, mumps, German measles, and poliomyelitis. The most effective way of using human convalescent serum is to give a large enough dose at one time, as early as possible, by intravenous injection. It is less effective by the intramuscular route because of the delay due to absorption. The intraperitoneal route is effective, but this method of administration has, in the opinion of Dr. Thalheimer, not been used so widely as it should be. There appears to be no danger from the incompatible agglutinins in pooled

If you have a ward epidemic, for instance, with children who have been exposed to measles and you are looking out for secondary cases, watch the thermometer first and the eyes second, and you can spot the new cases before the Koplik spots appear. If in those early stages you give the convalescent serum in doses of 40 to 50 cc intravenously, you can possibly modify the oncoming measles.

I want to make one more point, and that is the cost of scarlet fever serum which must affect the treatment. Last year there were 350 cases of scarlet fever at one time in Willard Parker Hospital, and we discharged 700 cases before we had a death from that disease. Scarlet fever, even if untreated with serum, is, therefore, a comparatively mild disease nowadays. Convalescent serum costs 25 cents per cubic centimeter. If an adult gets 100 cc, that is \$25. Scarlet fever horse serum costs from \$8.00 to \$10 per dose. When you have 350 patients in the hospital, unfortunately you just cannot afford to give serum to every case.

Theoretically, it is desirable to give every early case of scarlet fever a therapeutic dose of serum. As for the cases that come in on the fourth or fifth day of the disease and who have already begun to get well, one is justified in watching and seeing how they get along. They will probably recover without further trouble.

DR DUBOIS: Are there any questions from the audience?

DR C H WHEELER: I should like to ask Dr Thalhimer if he would discuss briefly the indication for convalescent serums in other diseases, such as chickenpox and mumps.

DR THALHIMER: In the case of mumps, I think that the evidence that has accumulated is suggestive of its having a protective value, but it is not yet convincing. More work has to be done.

I think the situation is similar in the case of the prophylaxis with large amounts of serum in the early stages of whooping cough.

In a trial of chickenpox convalescent serum at the Willard Parker Hospital, even where 40 to 60 cc were administered, we could not demonstrate statistically that we had accomplished anything.

While I have not worked in the field of German measles, the reports in the literature indicate failure to prevent German measles.

DR DUBOIS: What is the situation with regard to poliomyelitis?

DR THALHIMER: Maybe Dr Stimson will state his experience.

DR STIMSON: Poliomyelitis convalescent serum is not used at the Willard Parker Hospital. We have a low mortality rate from the disease there, as low as at any hospital, and we use none either for therapy or protection.

With regard to pertussis serum, if I may add a word, babies in the first three or four months of life do not respond to any vaccine—such as vaccines for whooping cough—and, if exposed to whooping cough, they are liable to have a serious disease. The only thing one can do to protect them is to try to give them a considerable amount of serum. In Philadelphia at the University of Pennsylvania, they have lyophil and hyperimmunized serum which is being used. If I had a little baby who was exposed to whooping cough, I certainly would make a great effort to get some of that serum.

DR E A. KABAT: Are the human serums available commercially?

DR THALHIMER: No, not commercially. There are a number of laboratories throughout the United States which are nonprofit organizations and dispense these serums at actual cost of production.

DR KABAT: Can you get pertussis serum in New York City?

DR THALHIMER: Not from us, because we feel that the demonstration of the efficacy is not sufficiently clear. If we were to dispense it, it would be tantamount to our holding that it is efficient.

DR DUBOIS: Can convalescent serums be obtained upstate in New York?

DR THALHIMER: So far as I know they are not being produced in New York State anywhere other than here in New York City, but we have a federal license for dispensing serum, and we send it all over the United States by air express. Not infrequently we get calls from upstate.

Convalescent serum can be purchased from the Manhattan Convalescent Serum Laboratory, which is affiliated with the Department of Health and located at the foot of East 15th Street, Manhattan. Inquiries should be addressed to the laboratory—telephone GRamercy 3-8080, or STuyvesant 9-3100, Extension 2. Evenings, Sundays, and holidays call WOrth 2-6900 for information as to where serum can be secured.

DR McKEEN CATTELL: In instances where prepared serums are not available, do you regard it good practice to inject blood or serum from members of the family who have had the disease? What are the contraindications to that procedure?

DR THALHIMER: Blood or serum from

Medical Preparedness

Rehabilitation

Medical Bulletin No 5—June 30, 1941

UP TO June 30th, the Selective Service Administration of the New York City Area has examined 114,850. Of these, 49,435 were put in 1-A, fit for any of the rigors of military service, and 34,977 were put in 1-B, classified as fit for limited military service only.

It must at once be comprehended that from a standpoint of rehabilitation, a considerable number of men in 4-F will be found to have defects that medical therapy could correct and render them fit for full military duty. Furthermore, there will be found many classified in 1-B who are absolutely beyond the efforts of any medical care to render them fully competent for full military duty. This is inherent in the regulations which define these classifications.

The regulations classify the registrant as he is found physically at the time of the medical examination. Thus, a given registrant presents at that time a specific physical defect or defects. The classification under the Selective Service Regulations is only concerned with the answer to the implied question

Is he now able to perform, with the condition he now has, full military duty, limited military duty, or is he not able to perform any military duty?

The idea of rehabilitation has been a byproduct of the statistical study from the medical examination of the registrants coming under survey of the administration of the Selective Service Law. Because these medical statistics were accumulated during the period since the law became effective and were assembled with no ulterior thought in mind and with no idea of bolstering any program or plan for health measures, they undoubtedly furnish unbiased factual data on the state of health of a cross section of the male population in the range of age groups between the years of 21 and 35.

In a bulletin issued from this Medical Division, under date of April 15, 1941, I advocated the establishment of a procedure in rehabilitation. On March 31st the National Administration appointed a Rehabilitation Council to study the proposition and on April 16th the National Administration recommended treatment for remedial defects found upon our physical examinations.

In a program which was termed "Prehabilitation," the National Administration suggested that it be entirely elective on the part of the registrant to accept the proffered cure and stated that it would become effective because of a proposed educational campaign which would lead to a closer cooperation between the registrant and his local physician or dentist. Various ancillary medical bodies were integrated in the movement. The National Administration hoped that the new plan would materially reduce the percentage of rejectees for physical deficiencies and "by improvement of the health of young men of military age would tend also to better general public health."

Again, on April 25th, Selective Service Headquarters announced that they would distribute an educational pamphlet to registrants to "make yourself fit for service."

In spite of all these efforts, the situation in regard to rehabilitation has remained, to a great extent, unchanged in this area.

In the bulletin of April 15th, to which I referred above, I remarked that educational campaigns are not enough to make the obvious remedy practical and solve the problem. The concept that every citizen has an obligation to perform his military duty should be strengthened. I suggest that the Selective Service Law be changed to make it compulsory for a citizen to undergo curative therapy so that he could not hide behind his defect and avoid the obligation of military duty which the Selective Service Law now imposes upon him.

On May 23rd General Hershey, discussing curative measures to improve the general health standard, said that the registrants not yet classified "owe a duty to their government for service." He also stated that "obligation calls for the service of a whole man—a man entirely alive—a healthy, strong, well-developed man. It is the duty of the registrant faced with this responsibility to use every means available to make himself fit to serve."

General Hershey further continued "I do not believe our people will continue indefinitely to accept avoidance of military obligations by the class to which I have just referred. If this assumption is accurate, we are confronted with the necessity for rehabilitation for the members of this group where it is possible to better their physical condition. This group must be utilized in a manner which will not permit them to escape military obligations because of their physical condition."

Having these bulletins and recommendations in mind, an effort was made by this Headquarters to try a voluntary experiment in the area of one Local Board in Queens County where ancillary organizations were integrated to help the registrants rejected to quickly and easily secure medical service to relieve remedial deficiencies. This effort has been going on for two months but I note no marked reaction accompanying this effort. More positive methods of persuasion evidently are necessary to ascertain whether or not voluntary efforts at rehabilitation are capable of producing an improvement in the health standards of these groups of men found physically below standard for acceptance into military service.

The organized medical profession has contended, for a long time, that availability of medical care was adequate enough in our area and that many people would refuse its benefits even were it put upon their doorstep. In acute distressing illness, obviously every one seeks relief. But in the category of the aftermath of

human convalescent serum when it is injected intravenously into patients, and as much as 2,000 cc of such serum is given intravenously without reaction

Scarlet fever and measles are the two diseases in which human convalescent serum has proved most effective. They are not available for distribution by commercial firms but may be secured through the Manhattan Convalescent Serum Laboratory, which is affiliated with the Department of Health of New York City

In scarlet fever the serum can be used for prophylaxis as well as for treatment. An intramuscular dose of 20 cc will completely protect about 8 out of every 10 children against scarlet fever. The others usually develop a mild form of the disease. The serum will also abort scarlet fever in most patients when it is so given within the first thirty-six hours of the onset, in intravenous doses varying from 20 to 100 cc, depending on the age. Complications are less severe and their incidence is diminished. One problem is the cost of human convalescent serum, which amounts to about \$25 for a 100-cc dose necessary for an adult.

It was pointed out that animal scarlet fever antitoxin is also effective but less so. This is given only by intramuscular injection.

In measles, human convalescent serum appears to be of importance only for prophylaxis. It produces a beneficial effect in about 99 per cent of the cases. About one-half to three-quarters of the children will escape the disease if the serum is given not later than the seventh day after exposure. In most of the others it becomes such a mild disease that it is sometimes difficult to make the diagnosis. When the disease is completely prevented, the immunity begins to wear off in about ten days. It is, therefore, under most circumstances,

better to confer only partial immunity—that is, reduce the disease to a mild form—since the mild form of the disease produces lasting and satisfactory immunity. In the vast majority of children, measles will be a mild disease when the serum is given in the pre-eruptive stage, but once the rash has appeared, convalescent serum has a questionable influence on the course. The dose is not less than 5 cc by intramuscular injection, in infants up to 1 year, up to 20 cc in older children. If it is not feasible to use convalescent serum, blood or serum from members of the family may be administered intramuscularly for the prophylaxis of measles. The dose is four times as large, and eight times as large if the whole blood is used.

In the case of mumps there is some indication that a dose of 20 to 30 cc of convalescent serum will prevent this disease, but the evidence is not entirely satisfactory.

Dr Stimson is in favor of the use of convalescent serum for whooping cough, since it is such a serious disease in young infants, but Dr Thalheimer does not believe its efficacy is sufficiently established.

Also there seems to be some question about the value of convalescent serum in poliomyelitis. It is not used in the Willard Parker Hospital, where the mortality is as low as elsewhere.

Tetanus toxoid for immunization against tetanus seems now to be an established procedure. It is widely used and is effective in the prophylaxis against tetanus, although it is not fully trusted since injured individuals still receive antitoxin as well.

Various interesting points relating to the preparation of human convalescent serums, their mode of action, their dosage, theoretic aspects of their use, and public health aspects were discussed.

A STRIKING CONTRAST

How many people know that the doctors who serve the local draft boards give their services absolutely free? This takes much of the time of doctors in every part of the country. It has been granted generously, with no thought of reward. The young men who are being taken for the nation's defense have the satisfaction of knowing they are receiving the best medical examinations of any army recruits anywhere in the world.

How striking is the contrast between the attitude of the doctors in giving this invaluable service and the attitude of those crafts and trades that have endangered the defense program through strikes and jurisdictional disputes.

—*New York North Side News*

THE FEAST—by DR. SAMUEL BRICKNER
Reprinted in The Saranac Lake News by the author's request, the day before he died

There is no more Lucullan feast than this

At which I daily sit,
Laughter and sunshine, love, a tender kiss—

These are the sweets of it

If by chance, black stormclouds lowly bend

My unresisting head,

It is no symbol that my joy shall end,

For still my feast is spread.

A day will come, with laughter just as sweet,

The sun will fill the air,

Love still be young but other lips will meet

I shall have had my share.

—J A M A

ner of its being done and by whom it shall be done.

In other words, he should be compelled to take the cure for his deficiencies if medical opinion believes the deficiency can be cured. He shall have the election of *who* shall do it and *where* it shall be done. He may elect to have it done by a physician of his own choice, and pay for it, he may elect to have it done at a voluntary or a municipal hospital or clinic, under rates to be arranged by Selective Service in the same manner as the laboratory fee schedule was arranged for, by mutual agreement of the hospital authorities and Selective Service. As a last resort, the man failing to elect employing any of these courses shall be taken into the Army under a condition to be termed "*Provisional Induction for Rehabilitation*" and an Army hospital with its staff shall undertake the rehabilitation.

The Army hospital designated to receive these provisionally inducted men, need not be a fixed, regular Army hospital, although it may be. A hospital in this area might be staffed by Medical Reserve Officers who are at present upon an inactive status because they have assignments to Army sponsored medical hospital units, or because they are of an age not acceptable, at present, for full Army medical field work. There are many such officers available in this area. They constitute a pool of "frozen medical assets" under present existing conditions and regulations.

To utilize them in the suggested manner, would free these "assets" and make many highly skilled and capable men available for this work, who have already made a record of patriotic contribution since they have taken a degree of medical military training. Some have very creditable records of prior periods of service during the last war.

Were this type of hospital for those "provisionally inducted for rehabilitation" located within the city area, the costs could be lessened greatly by having the Army medical duty carried on upon a part-time basis. Furthermore, I have received, at various times, tender of their facilities from some of the voluntary hospitals in this city. Pavilions from such grade A institutions would be usable to house sections of such a rehabilitation medical unit.

I believe that once the work to organize such a service were given, the organization of the service within the city area would not present a very great problem. The profession, and the ancillary medical organizations here in New York, are eagerly anxious to help, not only the goal set for Selective Service, but also the rehabilitation of the class group herein discussed.

Just as soon as the man is ready for discharge from these special rehabilitation sections of existing hospitals, or from the Army rehabilitation hospital, he shall then be sent to a convalescent camp which should be established in this area. It is not good practice to keep convalescent men in a hospital atmosphere longer than absolutely necessary for medical care. Therefore, the camp for convalescence should be some distance away from the hospital proper.

At this camp, gradual body-building exercises and graded physical training should be given and the registrant shall undergo this process of training and hardening until he is fully fit, and then be transferred into the Army under the provision of full induction, to take his military training.

I am more inclined to carry on this experiment with a limited group to gain experience as to how it would work. There is every reason to believe it would work well.

Meanwhile, study should be continued upon this problem, the whole question of how to bring people needing remedial therapy to *accept* it on a voluntary basis, provided means were at hand to deliver it to them, is one of the unsolved questions in our medical field today. This is a problem to which the medical profession has often directed attention.

From the factual data at hand at present, it is reasonable to assume that almost exactly similar percentages of physical defects are present in those of the same age group who, because of family dependencies and other legal deterrents, are deferred and are not at this time being physically classified. Figures on these are not available at the Medical Division. They total, in the aggregate, to May 1st, 288,398 white and 11,408 Negroes. Upon these, no physical examination has been made.

If military training is to give to those who undergo it—as we believe it will—a stronger, healthier body to meet the demands of life when they are returned to their wonted civilian status, the problem presented by the physical deficiencies among those whom the law at present leaves free to go their own way, will be still greater, for these men will find themselves doubly handicapped when they come, as they must, into competition with this stronger, healthier group in business and industry—when the present emergency will have passed and become history.

Good, sincere planning for the achievement of even better health levels and physical standards in our population over and above the extremely fine level of health which our country now possesses in comparison to that found anywhere in the world, must not leave out of account these factors.

However, our present paramount concern is focussed on procurement of effective manpower for the Army. To render those now among the physical discards from this patriotic service, available for military duty, will be to begin to solve the problems herein outlined.

The groups outside the provisions of the Selective Service Law—because deferred—must await the results obtained through experience gained with the groups of men which are our present concern.

To actually begin the process of rehabilitation among this group, for military service, will give us the experience we need, to base a program on facts and not on theories when we come to consider the necessities which the problem presents for civilian workmen.

SAMUEL J. KOPETZKY
Colonel, MC, Medical Division

such acute illnesses and the ensuing chronicities where the lesion is not actually disabling, if gainful occupation can be continued at the time, reluctance to accept therapeutical relief has been the rule, observers and heads of Hospital Departments and Clinics have found. What these defective registrants cannot, and do not, realize is that with the advancing years these disabilities increase.

A recently published bulletin from this Headquarters, on a survey of age groups (*Medical Bulletin No. 4*, Selective Service Headquarters, New York City, May 9, 1941), shows that of 37,329 in the ages below 25 years, 22.4 per cent were found fit for limited duty only and 18% were totally disqualified for such duty.

The percentages of disqualifications increase in each successive age group. Thus, in the age group between 26 and 30 years, among 25,900 registrants, 47.9 per cent were available and accepted for Army duty, 28 per cent were able to do limited service, and the disqualified reached 23.8 per cent. In the age group between 31 and 35 years of age, the figures were still higher. There were 19,336 registrants in this group. Of these, 35 per cent were accepted for full military duty, 34.85 per cent fell into the 1-B classification (limited duty), and 29.2 per cent were rejected as unfit. This study comprised a survey of 87,085 registrants up to and through the eleventh induction quota call.

If this survey of medical statistics is a fair sample of what is being uncovered throughout the country, then it must be evident that this sample finding has connotations of pertinence to the employment problem. With advancing age, the handicap due to physical defects increases, and one has a right to assume that eventually the man thus handicapped drops from employment and, in the end, becomes one of the group of unemployables.

Thus, rehabilitation is concerned with more than military obligation, for it has ramifications in civilian productive endeavor and industry. At this time the exigencies of the military training program play a major role, and, while it seems proper to indicate other implications which remedial medical deficiencies inherently entail, that aspect of a rehabilitation program dealing with the problem of making unfit men fit for military duty is our primary concern at this moment.

Therefore, an intensified effort to use persuasion to have the unfit men voluntarily accept and undergo remedial therapy has been started in the New York City Selective Service area of jurisdiction. With the approval of the New York City Director, Colonel Arthur V. McDermott, a city-wide effort is now under way.

Accepting the proffered aid of the North Atlantic District Branch of the American Association of Medical Social Workers, at each of the 280 Local Boards there will be a social worker trained in interviewing people needing medical service. These social workers are trained in comprehending the necessities of funds for home (rent) and family income. They daily have to determine the ability of patients to pay fees in the hospitals and clinics of New York City where they habitually work. They have an acute awareness of those entitled to free and part-pay medical care. This knowledge and

technical ability they have volunteered to the New York City Selective Service Administration. The offer of service was gratefully accepted.

The plan would function along the following lines:

At each Local Board there will be one of these volunteer social workers who will make contact with the registrants classified in both 1-B and 4-F. A blank has been prepared which the registrant will fill out with the aid and assistance of the social worker. On this blank, among other things, the registrant will be asked:

Will you accept remedial therapy from your own private physician? Give name of your private physician.

If you are unable to employ a private physician, will you use existing facilities in hospitals, voluntary or municipal, which have extended their facilities for this work to you, to have your defects corrected?

At this point information will be elicited as to the reasons why the registrant refuses to accept remedial therapy from either his own physician or from existing hospital and clinical facilities. These social workers, because of their training, will be able to evaluate the reasons given and make a factual tabulation of the results of their inquiry.

In this way it is hoped to gather factual data on the number of registrants who will avail themselves of medical care if it were "brought to the door," speaking metaphorically.

These social workers have furthermore arranged to make visits to the homes of the registrants who seem recalcitrant, with the idea of persuading them to undertake voluntary remedial therapy. Then the task of persuading those found to be recalcitrant to the offers to help them will be undertaken. Visits to the home, talks with the wife or family and every other effort will be made to have the registrant voluntarily submit to having his correctable physical defects remedied.

When and if this work has been carried on for a length of time to warrant conclusions, I shall report further on this intensive, coordinated experiment in persuading those with obvious remedial defects to correct them voluntarily. However, I am still of the opinion that the larger majority of registrants will not avail themselves of the medical care which will be tendered to them—for very obvious reasons.

Therefore, I am prepared to offer, for future consideration, an alternate plan. This plan consists of an amendment to the Selective Service Law, to make it mandatory that an individual with correctable defects shall have remediable therapy undertaken, so that his correctable physical defects shall not permit him to avoid military service. I recommend this notwithstanding the fact that the majority of those disqualified for military service are engaged in gainful occupation at this time.

I would not have the compulsion in the proposed amendment to the Selective Service Law apply to the manner and means whereby the remedial therapy shall be carried out. The mandatory provision shall simply be directed to the end that the remedy shall be taken by the registrant, leaving him free to elect the man-

Medical News

County News

Albany County

The annual clambake of the county society will be held at the Albany Country Club on September 10. Available sports will be swimming, tennis, baseball, and golf.

Bronx County

The county society elected the following officers at its meeting on June 18:

Drs. Abner Stern, president, Morris Cohen, president-elect, Frederick W. Williams, vice-president, Henry Friedland, secretary, Samuel Epstein, treasurer, Frank LaGattuta and Louis Steinbach, censors, Harry Projector, chairman of the Medical Economics Committee, Edward R. Cunniffe, chairman of the Legislation Committee, John B. Schwedel, Public Health Committee, and Henry Barrow, Public Relations Committee.

Drs. Moses Krakow, Edward R. Cunniffe, I. Lewis Amster, and Emil Koffler were elected delegates and Drs. Vincent Hayward, Frederick Williams, Renato Azzari, and Samuel Leo were elected alternates. Dr. Harry Aranow was elected to the board of trustees.

A paper was read by Dr. Ira S. Wile on "The Problem Child, Medical, Psychological and Social Aspects," with a general discussion.

The Public Health Committee is preparing to give postgraduate courses in physiotherapy, heart disease, and traumatic surgery.

The course in physiotherapy will consist of four to six lectures on the principles and methods applying in arthritis, peripheral vascular disease, sprain, trauma, and infections.

The course in heart disease will consist of seven or eight lectures covering its various aspects and will be given by Bronx County physicians who are members of medical and teaching staffs.

The course in traumatic surgery will consist of eleven sessions, and the subjects covered will include shock, burns, wounds, fractures, infections, sciatica and low back pain, bursitis, chest injuries, and diabetic extremities.

Chautauqua County

The tenth annual interstate summer meeting of the Chautauqua County Medical Society was held at the Chautauqua Institution on Chautauqua Lake on July 30. The excellent program and beautiful site made the day a most enjoyable one for the doctors, their families, and friends.

The program was as follows: "Treatment of the Menopause," round-table discussion, by Dr. Louis A. Siegel, chairman, Dr. Francis D. Leopold, and Dr. Gilbert M. Beck, of Buffalo; "Present Status of Chemotherapy"—medical aspects by Dr. Arthur C. Ernestine and surgical aspects by Dr. George Crile, Jr., of Cleveland; aspects by Dr. George W. Cottis, of Jamestown, New York; Dr. George W. Cottis, of Jamestown, New York, president-elect of the New York State Medical Society, opened the discussion, "American Medicine Prepares," by Dr. Morris Fishbein.

Luncheon was served in the Hotel Athenaeum,

and in the afternoon Dr. Fishbein spoke on "Medicine Moves Forward." This address was open to the laity. There was an afternoon concert by the Chautauqua Symphony Orchestra with Albert Stoessel, conductor, and Joan Peebles, contralto, as guest soloist. An evening concert was also given by the Orchestra. A golf tournament, held in the afternoon, provided much entertainment.

Chemung County

The annual outing of the county society was held Wednesday, July 2, at Cold Brook Club.

The outing was preceded by a golf tournament at the Elmira Country Club for the Doctor's Cup.

Activities at Cold Brook Club started at 3:30 p.m. with a doubles quoit tournament and a softball game with University of Buffalo alumni pitted against "the rest of the world." A steak dinner was served at 7:00 p.m., followed by a singing bee in charge of Dr. Joseph S. Lewis. The program announced that a lie swapping contest would run throughout the afternoon and evening.

Erie County

Designed to give more adequate medical care to Buffalo relief clients and at the same time to compensate physicians, the County Welfare Department's new medical plan became effective on July 1.

Welfare Commissioner Thomas W. H. Jeacock announced the appointment of five physicians as medical examiners, four pharmacists, and the transfer of four junior case workers as medical social workers.

The medical investigators who each will receive \$1,560 a year are: Dr. James E. Short, 303 Abbott Road, Dr. Jerome W. Romano, 468 Delaware, Dr. Roy C. Fisher, 625 Parkside Avenue, Dr. Richard M. Gardner, 131 Linwood Avenue, Dr. Harry Spiegelman, 532 East Ferry Street.

The pharmacists, to be paid \$1,200 annually, are: Theodore Stopen, Helmut, Frank C. Luango, Hamburg, Stephen N. J. Rubach, 1322 Sycamore Street, Louis E. Kramer, Gardenville.

The medical social workers whose salaries will be \$500 are: Mary A. Clark, 334 Rodney Avenue, Henrietta M. Hunt, 94 Freund Street, Anne M. Wherley, Lakeview, and Mildred E. Ahl, 424 Ashland Avenue.

Jefferson County

Dr. Daniel L. Borden, Washington, D. C., surgeon, was the guest speaker at the meeting of the county society at the Black River Valley Club on June 24. About 30 physicians attended. Dr. Borden, as president of the District of Columbia Medical Society, was an important witness in the law suit involving his society in a defense against socialized medicine tried in Washington during the past winter.

Kings County

An article in the *Brooklyn Citizen* by Dr Charles F. McCarty, director of the medical activities of the county society, says in part

"The physicians of Brooklyn have responded to the present national emergency the same as they always have in the past. Over 937 physicians are, at present, serving the Government. A great many have given up their practices and are on active military or naval duty, while many more are serving as local draft board examiners or members of medical advisory boards.

"All physicians who serve as examiners on local draft boards or on medical advisory boards, serve without pay. Each member of the advisory board works from three to five hours per week. The number of physicians on local boards varies from one to six. The work of examining the men who are to be selected for military service for each of the local boards takes about twenty hours per week.

"All health matters connected with national defense are under the jurisdiction of the Committee on Military and Naval Affairs of the Medical Society of the County of Kings. The committee consists of Drs Thomas A. McGoldrick, chairman, Charles F. McCarty, secretary, John B. D'Albora, Maurice J. Dattelbaum, Edwin A. Griffin, John J. Master-son, William C. Meagher, Daniel A. McAteer, Philip I. Nash, Irwin E. Sims, and Thomas B. Wood.

"In order that the civilian population may be cared for in an emergency, the Medical Society of the County of Kings and Academy of Medicine of Brooklyn has conducted a survey of the hospitals of Brooklyn and has found that by using corridors, recreation rooms, reception rooms, and other available space in an emergency, the capacity of the hospitals can be increased by 3,313 beds. They have also found that nineteen hospitals are willing to provide catastrophe units. These will consist of physicians, nurses, and attendants with the necessary ambulances, instruments, and supplies to work outside of the hospital in a serious emergency.

"At present, the county society has a record of 340 physicians in Brooklyn who are in active military or naval service.

"Among other defense duties recently assigned to the county society are those of assisting the Red Cross in establishing a dry plasma bank and of assisting the Government in nutrition. The Brooklyn Chapter of the Red Cross is obtaining blood from donors in Brooklyn. The plasma of this blood will be dried and stored for use in a national emergency. The society has selected a panel of twenty-five physicians who will do a physical examination on these donors in order to determine whether they are capable of giving the blood. These doctors will serve without pay. A committee on nutrition of the society is also being formed. This committee will be composed of physicians who have specialized in diet and nutrition and will inform the public as to the type of food, obtainable in an

emergency, which may be used in order that all persons may be properly nourished."

The county society will give a dinner for its living ex-presidents at the Hotel St. George on January 17, 1942.

Nassau County

The Health Exhibit being prepared for the Mineola Fair, September 9 to 13, by the Nassau County Medical Society under the direction of J. Louis Neff, executive secretary, will become a permanent county institution, according to plans now being formulated by Mr. Neff. A permanent headquarters in a central location is now being sought, all as the result of the tremendous interest in public health created by the New York World's Fair health display. Mr. Neff is being aided by committees of the following Nassau County organizations in the preparation and handling of exhibits at the Mineola Fair, and due to the importance of the exhibit an entire wing of a building has been assigned by the Queens-Nassau Agricultural Society for the displays. Cancer Committee, Dr. Richard Derby, chairman, Dental Society, Dr. Herman Weinstein, president, Health Department, Dr. Earle G. Brown, commissioner, Medical Society, Dr. Charles W. Martin, president, Mental Hygiene Committee, Mrs. Henry Hill Anderson, chairman, Nutrition Committee, Miss Irma Bradford, chairman, Public Health Nursing Council, Mrs. Francis Gilbert, president, Tuberculosis and Public Health Association, Mrs. George E. Brower, president, and Woman's Auxiliary to the Medical Society, Mrs. Byroa D. St. John, president. Helpful questionnaires and trained consultants will be features of the exhibit.

Oneida County

The Utica Academy of Medicine held its annual outing at the Teugega Country Club at Rome on June 19. The afternoon was given to golf, with dinner at 7:30. The speaker was Charles John Stevenson, Philosopher—Humorist—Newspaper Editor—Radio Commentator—Lyceum Lecturer, and his subject was "Doctoring with Pleasure."

Ontario County

The third quarterly meeting of the county society was held in the Geneva Country Club on July 8. Dr. A. D. Kaiser, professor of pediatrics at the University of Rochester, spoke at the scientific session following dinner on "Rheumatic Disease in Childhood."

Otsego County

The county society held its regular quarterly meeting on June 11 at the Cooper Inn, Cooperstown. The final lecture of the 1941 post-graduate series was given by Dr. J. Hamilton Crawford of Long Island College of Medicine on the topic, "Some Common Problems in Cardiac Diagnosis."

Warren County

A motion picture, "Anemias," was shown at a meeting of the county society on July 2 in The Queensbury at Glens Falls and was at-

STERILIZATION OF THE AIR BY A GERMICIDAL MIST

The effective sterilization of air by a germicidal mist is reported in *Science* by Drs O H Robertson, Edward Bigg, Benjamin F Miller, and Zelma Baker, of the University of Chicago Medical School, notes the *Medical Record*. According to Dr Arthur C Bachmeyer, associate dean of the Division of the Biological Sciences of the medical school, the method promises to achieve sterile air in sick rooms and crowded places, as well as in industrial fields, and to reduce markedly the spread of such infections of the upper part of the respiratory tract as pneumonia and common colds. Its possible applications in war conditions are widespread, according to Dr Bachmeyer, particularly with regard to the problem of germ-laden air in such places as air-raid shelters and barracks. Two medical groups in England are already working in this field, though their results in war experiences have not been reported.

The germicidal mists, or aerosols, found effective by the investigators, consist of minute droplets of propylene glycol. The effectiveness comes from the fact that each droplet of the aerosol contains the same concentration of the effective chemical substance as does the parent solution and, therefore, the antibacterial agent is

enabled to act in high concentration on bacteria suspended in the air. In the quantities employed the product appears to have no poisonous effect on humans.

These investigators tested both the spraying of the mist on bacteria and the spraying of bacteria into the mist, which would be tantamount to a cough or sneeze. They found the mist effective in destroying the bacteria in both instances.

Hitherto, sterilization has been effected by the application of germicides to germ-laden objects (such as floors, furniture, or instruments) by fumigation, or by ultraviolet rays. In the first method the air is not affected. In the second, the fumigating compound is poisonous to humans as well as germs and cannot be used to kill the bacteria in the presence of humans. Dr Bachmeyer suggests that the aerosol method is likely to be more effective and less costly than the ultraviolet ray equipment. While the effectiveness of the germicidal spray in the reduction of diseases of the upper part of the respiratory tract cannot be gaged accurately without extensive clinical studies, he said, the approach is in keeping with efforts of scientists to prevent as well as cure disease.

Q. Are the proteins of canned meat of high biological value?

A Oh yes Canning does not influence the biological values of proteins And, of course, the proteins of meats are excellent sources of the essential amino acids (1)

HOW COME—A SANITARIUM?

The private practitioner may wonder at times what circumstances or impulses lie back of the establishment of an institution in the care and treatment of certain cases

To many persons, a change of business or business location merely signifies a failure or a move to a more lucrative field. In a mercenary world of their own, it is unconceivable to such people that any human being might make a change primarily to serve others better or to provide a service to others that they have been unable to obtain.

Yet there are such individuals and we hear of them continuously in science and medicine. We find it often a case in medical men who devote their lives to providing special sanitariums for the service of their colleagues

The medical director of an excellently planned and operating institution explains the creation of his sanitarium as the realization of a community need. In his own words, after nine years of private practice he felt compelled either to drift unhappily with make-shift facilities available or establish a hospital unit where proper and scientific care could be developed for certain types of patients who require special "operating settings"

The undertaking cited is not an exception. Most of the fine institutions serving the medical profession have been inaugurated because of equally fine motives

Of course it takes more than a "fine motive" to make a useful service, but it does help and does serve to establish greater confidence in the efficiency of the service

Hospital News

Defense Demands Causing a Nurse Shortage

HOSPITALS around the state are reporting that the defense demands are draining away their supply of competent nurses. As one newspaper puts it, "the American nurse, angel of mercy, ministering to the sick and wounded, whose courage and skill have made her an idolized figure and blazed her name on the pages of history in every struggle that the nation has faced, is answering the call for 6,000 of her profession," and the shortage of nurses "is moving into the acute stage."

To take one example out of many, "the Syracuse hospitals find themselves facing a shortage of trained registered nurses that is daily taking on more serious proportions," reports the *Post Standard* of that city.

University Hospital Hard Hit

It seems that while every hospital is feeling the loss of its trained nurses, University Hospital is the hardest hit.

Dr. Louis M. Hickernell, superintendent, said that the number of nurses who have left that hospital has made it necessary to close one of the smaller pavilions, which means that all of the beds in it must remain empty.

"This hospital, like every other hospital in Syracuse, is anxious to cooperate 100 per cent with the national defense program," said Dr. Hickernell, "but our situation as to a sufficient supply of experienced trained nurses is taking a serious turn. With industry working at top speed and pressure being applied to keep it so, the home front must receive serious consideration."

"Undoubtedly we are going to lose many more of our trained nurses. War has a glamour for them as it does for all patriotic citizens when the nation and its liberties are threatened."

"This emotional disturbance often blinds one to other duties. Unquestionably we must have some trained nurses at home. It takes courage to go to war, but it often takes more courage to remain at home," he remarked.

"Our span of life has been steadily increasing. In the past 150 years the average span has risen from 31 years to 62 years. There has been a rise since the last war. This means that every community has more older people than in years past and old people are more likely to become ill than young people. Then we have these added men in high speed industry and every walk of life living under a tremendous strain."

Male Nurses Help

Dr. Hickernell said that at University Hospital work of the depleted staff of trained nurses is being lightened as much as possible by male nurses and by men who are being enlisted to assist in the capacity of orderlies. Practical nurses from schools in Rochester and Albany have been brought in to assist. Other hospitals are taking steps to supply helpers for their trained nurses.

The hospital council, composed of members of the executive staffs of University, Memorial,

Crouse-Irving, St. Joseph, Syracuse General, St. Mary's, and City hospitals, in cooperation with the local Red Cross chapter, has conducted a volunteer survey and set in motion the organization of two groups, with Miss Miriam Curtis, superintendent of Memorial, as chairman of a committee on volunteer service subsidiary workers.

Group Organized

One group, the "Grey Ladies," already has been organized, recruited from the hospital auxiliaries. This group comprises 189 women who are taking a course of twelve lectures extending over a month's time. Mrs. Ralph Haven is chairman of this group. When they have completed their course they will be uniformed and take up their duties.

The "Grey Ladies" will have eight committees. The hostess committee will take over such duties as directing visitors at the hospitals, regulating visiting hours, and other functions. The visiting committee will work among convalescent patients, reading to them, writing letters for them, doing errands, and performing other services. The library committee will provide and aid in selecting books.

Work with Children

The children's committee will work among children patients. The ward, clinic, and secretary committee will take over such duties as answering telephones, taking and delivering messages, procuring charts from the record room, and assisting nurses in many other ways. The surgical dressing committee will make and prepare dressings. A sewing committee will sort, mend, and store linens, and the flower committee will collect, distribute, and arrange flowers, Miss Curtis explained.

This fall the more important hospital aid or "Pink Lady" committee will be organized through the Red Cross chapter. This committee will receive a short course of one hundred hours of intensive nursing training under a paid instructor which, it is hoped, the Red Cross chapter will be able to finance.

Another contemplated step is a call to trained nurses who have married and ceased the practice of their profession. It is probable, Miss Curtis said, that these trained women will be asked to volunteer their services for a few hours a day, and it is expected that if such a call is issued that there will be an excellent response.

Medical Care Offered in New Hospital Plan

COMPLETED plans for provision of medical, as well as hospital, care for persons of limited income are announced by the Associated Hospital Service, which serves 1,250,000 subscribers in the metropolitan area at a cost of 3 cents a day.

HOW COME—A SANITARIUM?

The private practitioner may wonder at times what circumstances or impulses he back of the establishment of an institution in the care and treatment of certain cases

To many persons, a change of business or business location merely signifies a failure or a move to a more lucrative field. In a mercenary world of their own, it is inconceivable to such people that any human being might make a change primarily to serve others better or to provide a service to others that they have been unable to obtain.

Yet there are such individuals and we hear of them continuously in science and medicine. We find it often a case in medical men who devote their lives to providing special sanitariums for the service of their colleagues.

The medical director of an excellently planned and operating institution explains the creation of his sanitarium as the realization of a community need. In his own words, after nine years of private practice he felt compelled either to drift unhappily with make-shift facilities available or establish a hospital unit where proper and scientific care could be developed for certain types of patients who require special "operating settings."

The undertaking cited is not an exception. Most of the fine institutions serving the medical profession have been inaugurated because of equally fine motives.

Of course it takes more than a "fine motive" to make a useful service, but it does help and does serve to establish greater confidence in the efficiency of the service.

HALCYON REST

764 BOSTON POST ROAD, RYE, NEW YORK

[Continued from page 1596]

The new plan, announced by Dr S S Goldwater, president of the service, will give subscribers hospital care and service in wards and will pay physicians' fees for the hospitalization period.

Hospitals and physicians in New York and 11 neighboring counties have been invited to participate in the program. Dr Goldwater said that subscribers will be admitted as soon as a sufficient number of hospitals and doctors have been enrolled.

The combined service will be limited to individuals earning \$1,200 a year or less, couples with a combined income of \$1,680, and families with \$2,100

Community Medical Care Inc, a new organization representing the physicians, and the Associated Hospital Service will share the fees equally

The counties in which the service will operate, in addition to the five of New York City, are Nassau, Suffolk, Westchester, Putnam, Dutchess, Columbia, Ulster, Orange, Rockland, Sullivan, and Delaware

Cost to subscribers will be only slightly higher than that now charged for hospital service alone. Individuals will pay \$12 a year and families \$27, regardless of the number of children. Maternity care is included in the latter rate.

The present plan costs an individual \$9 60 a year and a family \$24.

Newsy Notes

The Oneida City Hospital has purchased a new x-ray machine at a cost of \$9,880

. . .

The Onondaga General Hospital has a new ambulance, described in the local press as "a veritable hospital on wheels"

. . .

The Roosevelt Hospital, New York City, in conjunction with its Allergy Department has opened a new eczema clinic for the study and treatment of eczema from infancy to six years of age. The clinic is held on Wednesdays from 9 30 to 11 00 A.M.

Prize Essays

THE Merrit H Cash Prize and the Lucien Howe Prize will be open for competition at the next Annual Meeting of the Medical Society of the State of New York, April 27, 1942, in New York City

The Lucien Howe Prize of \$100 will be presented for the best original contribution on some branch of surgery, preferably ophthalmology. The author need not be a member of the Medical Society of the State of New York.

The Merrit H Cash Prize of \$100 will be given to the author of the best original essay on some medical or surgical subject. Competition is limited to the members of the Medical Society of the State of New York, who at the time of the competition are residents of New York State

The following conditions must be observed

Essays shall be typewritten or printed with the name of the Prize for which the essay is submitted, and the only means of identification of the author shall be a motto or other device. The essay shall be accompanied by a sealed envelope having on the outside the same motto or device and containing the name and address of the writer

If the Committee considers that no essay or contribution is worthy of a prize, it will not be awarded.

Any essay that may win the prize automatically becomes the property of the Medical Society of the State of New York "to be published as it may direct."

All essays must be presented not later than February 1, 1942, and sent to the Chairman of the Committee on Prize Essays of the Medical Society of the State of New York, 292 Madison Avenue, New York.

GLENMARY SANITARIUM

For individual care and treatment of selected number of Nervous and Mental cases. Epileptics and Drug or Alcoholic addicts. Strict privacy and close cooperation with patient's physician at all times. Successful for over 50 years.

ARTHUR J. CAPRON, Physician-in-Charge

OWEGO, TIOGA CO., N. Y.

PASTIME FOR INVALIDS

Sanitariums are well able to supply diversions for invalids and convalescents. It isn't always so easily and efficiently taken care of when the patient is confined to his or her own house.

Every physician knows how irksome an illness can become especially in the stages when pain and immobility are less acute. Yet this need not be made a time of thorough misery even in the home nor should the patient be permitted to indulge in absolute inactivity.

Prescribing amusement may appear a trifle far-fetched to many physicians, although it is not unlikely that they would enjoy a good dose of this kind of medicine many times themselves. There are a thousand and one ways to banish monotony, and a physician might also add to his "how do you feel today?"—"what have you been doing?"

A physician recognizing how much a diverted mind can aid in speeding recovery would not hesitate to store up a good knowledge of simple amusements that he might suggest and change each day. Books and radio will pall if a person has to spend days reading or listening.

Sometimes, the patient will hit upon some simple amusement himself that may eventually prove to be not just a pastime but the foundation for a future life work when fully recovered. There is the case of a poorly educated man laid up with a broken leg. In some manner he discovered the idea of dictionary research

work. Perusing a page a day as religiously as some folks do the Bible, he marked down all words new and unusual to him. These he pored over the rest of the day. It is not at all strange and startling that this man became a most interesting talker after convalescence.

There are hundreds of other amusements just as inexpensive and constructive that are safe and untiring physically. And just as many that provide enough activity to keep muscles and joints supple. There are a number of simple handicrafts for both men and women, there are games and many objects that can be made from common and inexpensive materials.

Musical instruments (of a sane type) may also provide the means of whiling away time constructively. Correspondence courses are available when teachers are not.

If you do not feel up to being an amusement director, a word to a member of the patient's family will often serve as well. There are many books on the market that will provide pages and days of "something to do" for the man, woman or child who can't get about.

One of these books, published in England and compiled by a woman with keen interest in the matter, contains even such interesting items as character reading from the face, character told by handwriting, tricks with cards, training the voice, writing short stories, writing poetry, sketching with pen and pencil, and among many other suggestions a chapter on ten-minute amusements.

PINEWOOD

Route 100 Westchester County Katonah New York
Licensed by the Department of Mental Hygiene. Emphasizing diagnosis and treatment of Neuro-psychiatric cases. In addition to the usual forms of treatment (occupational therapy, physiotherapy, outdoor exercise, etc.) we specialize in more specific techniques. Insulin, Metrazol and Electro shock. OUR LATIN AMERICAN COLLEAGUES

In twenty Latin American countries, according to recent checked figures of a mail service company, there are 40,260 physicians, 12,700 dentists, 20,687 druggists and 3,753 hospitals.

In number of physicians they rank—Argentina 10,787—Brazil 10,203—Mexico 4,460—Cuba 2,992—Colombia 2,558—Chile 1,930—Uruguay 1,605—Venezuela 1,085—Peru 952—Ecuador 775—Puerto Rico 567—Bolivia 385—Salvador 368—Honduras 289—Dominican Republic 273—Guatemala 251—Nicaragua 243—Paraguay 238—Costa Rica 160—Panama 139.

Some comparison of the distribution of physicians in these countries may be made with our own country. Greater New York alone has some 3,000 more physicians than the top-ranking Latin American country. Yet the metropolis has 5,000,000 less in population.

In hospitals the same order of rank holds generally true with but a few changes. Argentina with 640 hospitals is about on par with New York State (exclusive of

Greater New York). In the Latin American countries there are only six with more than 100 hospitals. Thirty-two of our States contain more than 100.

In the number of dentists practicing in Latin America there is a greater shift in the order of rank. Mexico, third in physicians and fourth in hospitals drops to seventh in doctors of dentistry. Argentina again leading with a total of 3,713 has about the same number as our third ranking State—Pennsylvania, and about one-third as many as New York State complete.

In druggists, the countries rank practically the same as for physicians. Argentina leads with 5,217 and compares closely with our leading State—New York with 6,610. Panama with only 9 has twenty-seven less than the State of Nevada which ranks lowest in this country with its 36 drug stores.

We have a drug store to fill the prescription of every 25 physicians. Latin America has one drug store for every 2 doctors.

NEW YORK STATE JOURNAL OF MEDICINE

Copyright 1941 by the Medical Society of the State of New York

VOLUME 41

AUGUST 15, 1941

NUMBER 15

Editorial

You Can Lead a Horse to Water, but—

Under the title "Health of the Nation and National Defense" the *New England Journal of Medicine* for June 12, 1941, comments "Seventy per cent of the young men in this country are being judged by proper authorities to be physically unfit for 'full military service' It is for the medical profession on the one hand and the laity on the other to see to it that this percentage is materially reduced, not only in times of war, but also in times of peace"

With this conclusion we are in all-out agreement The *Journal* says further "It is idle to argue that the Army regulations are unduly strict, for in modern warfare there is no place save for those who can 'take it'" Modern warfare as we hear of it today was born in the laboratory of the revolution in Spain. Until 1938 the Army itself was nearly, if not completely, devoid of any of the reorganization and material necessary to the conduct of the high-speed warfare now being demonstrated in Europe. Since the demobilization of the armed forces in this Nation following the first World War, we have been seeking security of a material and pacifist character. This quest has been characterized by self-indulgence and easy living, a fatuous faith in all sorts of Magnot lines, wide oceans, government spending, and a firm belief in the validity of our Utopia.

National health cannot be imposed upon the people by the physicians. It must be desired by the people themselves

and attained with the advice and assistance of physicians and many other co-operating agencies. It is evident that the people have been satisfied until now with a state of national health based upon a low standard. Bad teeth and eyesight have in no way interfered with their ability to sign government checks, nor have their hernias or infected tonsils or perforated eardrums precluded the driving of automobiles or listening to good advice over the radio. We must not forget that we have been living in a civilized paradise in which everything has been made easy.

Then the sudden imposition of a rigorous physical examination by the Selective Service boards and the Army in a sudden abandonment of fatuity in favor of reality. And a hue and cry about rejections! These rejections have not changed the condition of the national health. It is just as good now, even better, if the falling national death rate is any index, as it has ever been. But it is suddenly being measured by a more rigorous standard. This standard is based upon the necessity in modern high-speed warfare of shutting men up in tanks or placing them in reconnaissance cars or "boneshakers" where their anatomies must withstand all the familiar gyrations of the well-known cocktail shaker many times magnified amidst the noise of guns, the dust, and fumes of hot oil and engine gases. Or it contemplates placing men in airplanes flying

at 400 miles per hour, diving at even greater speeds, and so on. Assuredly, men have to be able to "take it," and how! Certainly, the large percentage of rejections should be reduced by the employment of every agency at our command. But the drive to achieve this must have public acceptance and cooperation. The medical profession and the many agencies concerned with the betterment of the private and public

health have until recently geared their activity to the necessities of peace. Now that activity must be indefinitely increased. Without reason, the national health can be much improved with the active cooperation of the public but only, be it understood clearly, if the public really desires it and will do something about it. It is still only too true that you can lead a horse to water but you can't make him drink.

Strikes in Hospitals

Pittsburgh and Allegheny County in Pennsylvania have recently been the scene of strikes in hospitals. That such a situation could occur is extraordinary to say the least. It recalls the Boston police-strike threat of which Calvin Coolidge, then Governor of Massachusetts, said "There is no right to strike against the public safety—by anybody, any time, anywhere." Nevertheless, as reported in the *J A M A*¹ "In a strike called at the West Penn Hospital on April 18, maids, orderlies, and employees in the nurses' home, in the engineering division, and in the garages were called out, there were threats of violence, actual violence, and establishing of picket lines. The window of an ambulance leaving the hospital was smashed and, altogether, a serious situation was created affecting the lives and health of all the patients in the hospital. On April 19 a court of Allegheny County granted an injunction restraining the defendant and its members from interfering with, hindering, or obstructing the conduct and operation of the West Penn Hospital." Previously the *Journal* has referred to a decision by the Supreme Court of the State of Pennsylvania, which said on January 6, 1941 "A hospital is not an industry. It has not been the custom in the past to unionize hospitals. The effect of unionization and attendant efforts to enforce demands would involve results far more sweeping and drastic than mere property rights."

"The questions of profits for the employer or wages for the employees are not alone involved. It is not merely a matter of suspending operations, ceasing work, and stopping production, such as might be true in a steel mill or automobile factory. It is a question of protecting the health, safety and, in many cases, the very lives of those persons who need the service a hospital is organized to render."

The strike was called by workers associated with the Congress of Industrial Organizations. There was picketing, interference with the removal of garbage and the delivery of food, and the removal of patients who desired to use taxicabs.

Concerning this strike, a member of Congress is said to have inquired why the violators of the law in the State of Pennsylvania were not prosecuted by the proper authorities of that state. The Supreme Court of the State had said in January "The effect of unionization and attendant efforts to enforce demands would involve results far more sweeping and drastic than mere property rights. It is a question of protecting the health, safety and, in many cases, the very lives of those persons who need the service a hospital is organized to render."

"Not one of the hospitals," said the *J A M A*, "is engaged in any trade or business." Each of the hospitals concerned is a nonprofit, public, charitable corporation. The work of hospitals concerns the public safety. The public

safety includes that of union members, legislators, Supreme Court judges, garbage collectors, and labor leaders, as well as law-enforcement agents, their wives, and children. The kind of brutality and callousness that permits leaders of labor to carry the technic and practices of coercion into the work of hospitals does not seem to give a damn for the public safety and is exemplified by the recent California strike in a national defense

industry to control which the Army had to be called out.

Are we to suppose that in the future hospitals may have to be operated under protection of armed guards because of such unchecked rapacity? Occurrences of this kind may "involve a responsibility that reaches high in the government not only of the State of Pennsylvania but also of the United States." There is plenty of law, let it be enforced.

How Much Is Enough?

This Nation has always been considered fortunate in that it has had a superabundance of things, raw materials, manufacture, church buildings, and even bright ideas. At what point do they become a liability?

Medicine in America may well ponder this question. Because the answer involves physicians as well as laborers, politicians as well as producers of goods. For goods, government, and ideas become rapidly obsolete. The more you have of any of them the more obsolete equipment, physical and spiritual, you are apt to have on hand. And in a fast-moving world, obsolete equipment becomes a liability.

If you have enough government, for example, you can progress, if you have too much you become retarded by the weight of junk you must drag along by taxes which support but do not produce. If you have ideas enough you can keep the wheels of industry turning and men producing, if you have too many ideas men's minds become confused and tend to glorify the obsolescent past and the junk they knew or thought they knew to be worth something.

The present world revolution beneath the surface of its wars is a vast effort to jettison the obsolete. Even the wars are not so destructive as the fury of the political revision, the structural razing, which many will not see, and fewer still believe. How then will it be, how is it now with us who have too much of everything—

too much government, too many resources, too many ideas, too much luxury, even too much medicine? How much is actually needed? How much is obsolete?

We do not, will not, face the reality of the debt structure. And yet it is evident that henceforth we must do more with less. The waste must be eliminated and a real program of conservation initiated. Obsolete equipment, physical as well as intellectual and emotional, will have to go. It is a luxury we can no longer afford, it is expensive junk.

It seems to us that the Committee on Medical Economics of this Society might well initiate a study of what is now obsolete in medical practice and medical organization. How much junk, deadwood, and fardel have we allowed to accumulate, expensive ways of doing things which could be simplified, obsolete procedures rooted in custom which could be thrown out. How much duplication of effort exists in medical practice and procedure? A good many of these have been developed in an expanding peace economy. It is self-evident that some of them will have to be revised, perhaps scrapped altogether in a total war economy such as we shall see in the next few months swing into full stride.

It appears to us to be stupid to shut our eyes to self-evident necessity. What must be junked, what should be saved? What can safely be contracted, what services or practices or procedure should

be expanded? Government has given little or no leadership in this field of planning, we are not aware that responsible groups in organized medicine have thought much about it, much less done anything. Resources have been surveyed it is true, but who has studied the obsolete usages of medicine, who can say

with authority how many appendices, diverticulae, vestigial tails, and assorted junk we carry complacently along because we have always done so. How much is enough, and have we too much? Too much is vastly more dangerous than not enough, especially when it is obsolete

Physicians for Britain

During the meeting of the House of Delegates at Buffalo, 1941, a resolution was introduced [see *New York State J Med* 41 1278, Section 25 (June 15) 1941] instructing the Society to call upon the A M A for a statement of its policy with respect to foreign service for American physicians. This was favorably reported and passed. It was duly transmitted to the A M A.

The following facts were published in the *J A M A*¹ relating to this matter: "By June 23, 1,343 inquiries had been received, 643 applications had been mailed in response to the inquiries received, 69 physicians who applied had been rated as professionally unqualified, 67 had been pronounced professionally qualified, but of these 2 have withdrawn their applications, 52 applicants are awaiting the decision of the committee, and 33 have been pronounced eligible for a visa. Fifteen applicants are now in process of having physical examinations completed, and 17 have been pronounced physically fit. Actually 2 men have been granted United States passports and 15 have reached the stage where they are awaiting passports. The total figure of physicians apparently ready to go or likely to be made available is about 65, with an additional 25 still in process before the committee. This will mean that by the middle of July approximately 90 men will be the response to the request.

"Since the announcement was first made a statement has come from Great

Britain authorizing the acceptance of married physicians, who will be on the same basis, salary, and allowances as unmarried men except when the total pay for British married officers of the same rank exceeds that for American single men, in such cases the higher rate will then be paid. For the emergency medical service married men will be accepted on the same terms as are single men. The British Red Cross also announces that 10 women with equal qualifications will be acceptable on the same terms as are men. With these additional announcements 17 more physicians, formerly considered ineligible, become eligible."

The *Journal* comments further:

"The total response to the request from Great Britain is not especially gratifying. In explanation, it may be pointed out that American medical publications and organizations have been repeatedly informed that our own need for physicians is considerable and will be met only with the greatest of difficulty. Already one medical school has announced an increased enrollment of 10 per cent to meet the increased demand for medical men. However, increasing enrollments in medical schools will not make additional physicians available until six years from now. The news from abroad and from Washington seems to indicate constantly the threat of the entrance of our own nation into the war. This also has unquestionably influenced many physicians to withhold enlistment in any military service until the needs of our own country shall have been satisfied."

Medicine's Present Job

"What is there left," cries the *Nassau Medical News*¹ out of the fastnesses of the Long Island pine barrens, "in this changing world? One by one our old landmarks topple and fall. Bit by bit our accepted truths are found to be false, that which we have known to be false is proven true. Where do we stand? What comes next?"

When has medicine or anyone else ever known what comes next? The *Nassau News* quite properly foresees "constantly increasing demands made upon us physicians to serve with the armed forces difficulty in securing interns and residents for our hospitals", civilian doctors having "to assume a greater burden in the matter of house and office calls", and the necessity for "the training of the younger physicians against the day when they must be fitted into larger staff groups or take the place of men called away from the community by the war effort."

But this is somewhat aside from the question implicit in the observation that "Bit by bit our accepted truths are found

to be false," etc. If this is so, why do we physicians continue to teach the old truths? Why bother about it? The things we do are based on the "accepted truths", for we know no other kind. We are constrained to follow the only paths we know, and to teach the "accepted truth" in the sense that it has been proved by experience.

In a world full of labile propaganda, the truth, in a political sense, is what some group wielding power desires it to seem to be. It is not necessarily the same yesterday, today, and tomorrow, for, politically, truth is the servant of power and the handmaiden of ambition. From ancient times it has been asked "What can a man believe?"

Medicine's present job, aside from the practical one of caring for the sick, is the preservation and the teaching of the "accepted truths" amid the chaos and destructive influence of world revolution. It may have to be done in the debris of demolished things, from cellars and fox-holes, amid the ruins of civilization as we have known it, but it will be done, it is our job.

How to Live Longer

Survivors of the 175 graduates in medicine of the Class of 1900, College of Physicians and Surgeons, Columbia University, New York, averaging 67 to 68 years of age, are undertaking a novel experiment in preventive medicine. They have formed a committee of longevity to administer complete medical examinations to one another. There are 102 living members of the class scattered from Syria to Columbus Circle and points north, south, east, and west.

Can medical men prolong life expectancy? Here is a chance to find out. The members of the Class of 1900 not only hope to extend their average life expectancy, but to increase their comfort in living their longer lives. The experi-

ment may prove to be a notable contribution to the science of gerontology. The idea is so eminently sensible and practical that one wonders why it has not been previously tried. Physicians in all ages have experimented upon themselves for various reasons—to discover the effect of drugs, to try out methods of immunization, for example. The present experiment is one that logically follows the development and widespread use of health insurance from which, however, the average physician—or his estate—can benefit only in an economic sense.

When one examines the reasons why any group of men in these times should desire to live longer, one is forced to the conclusion that such reasons must be

be expanded? Government has given little or no leadership in this field of planning, we are not aware that responsible groups in organized medicine have thought much about it, much less done anything. Resources have been surveyed it is true, but who has studied the obsolete usages of medicine, who can say

with authority how many appendices, diverticulae, vestigial tails, and assorted junk we carry complacently along because we have always done so. How much is enough, and have we too much? Too much is vastly more dangerous than not enough, especially when it is obsolete

Physicians for Britain

During the meeting of the House of Delegates at Buffalo, 1941, a resolution was introduced [see *New York State J Med* 41 1278, Section 25 (June 15) 1941] instructing the Society to call upon the A M A for a statement of its policy with respect to foreign service for American physicians. This was favorably reported and passed. It was duly transmitted to the A M A.

The following facts were published in the *J A M A*¹ relating to this matter: "By June 23, 1,343 inquiries had been received, 643 applications had been mailed in response to the inquiries received, 69 physicians who applied had been rated as professionally unqualified, 67 had been pronounced professionally qualified, but of these 2 have withdrawn their applications, 52 applicants are awaiting the decision of the committee, and 33 have been pronounced eligible for a visa. Fifteen applicants are now in process of having physical examinations completed, and 17 have been pronounced physically fit. Actually 2 men have been granted United States passports and 15 have reached the stage where they are awaiting passports. The total figure of physicians apparently ready to go or likely to be made available is about 65, with an additional 25 still in process before the committee. This will mean that by the middle of July approximately 90 men will be the response to the request.

"Since the announcement was first made a statement has come from Great

Britain authorizing the acceptance of married physicians, who will be on the same basis, salary, and allowances as unmarried men except when the total pay for British married officers of the same rank exceeds that for American single men, in such cases the higher rate will then be paid. For the emergency medical service married men will be accepted on the same terms as are single men. The British Red Cross also announces that 10 women with equal qualifications will be acceptable on the same terms as are men. With these additional announcements 17 more physicians, formerly considered ineligible, become eligible."

The *Journal* comments further:

"The total response to the request from Great Britain is not especially gratifying. In explanation, it may be pointed out that American medical publications and organizations have been repeatedly informed that our own need for physicians is considerable and will be met only with the greatest of difficulty. Already one medical school has announced an increased enrollment of 10 per cent to meet the increased demand for medical men. However, increasing enrollments in medical schools will not make additional physicians available until six years from now. The news from abroad and from Washington seems to indicate constantly the threat of the entrance of our own nation into the war. This also has unquestionably influenced many physicians to withhold enlistment in any military service until the needs of our own country shall have been satisfied."

¹ J A M A 117 No 1, 37 (July 5) 1941

his being "employed as a physician at the hospital for about three months and among other duties" having had "charge of the institution pharmacy"

The story seems to indicate that investigation of the qualifications of employed physicians, at least by this employing hospital, was lax. In view of the

increasing shortage of narcotics due to disturbed conditions of trade, it is highly probable that more instances of this sort will occur. It should be a warning not only to hospitals but to all physicians who are practicing in the state to increase their vigilance where narcotics are concerned.

Special Article

Cooperating for National Defense*

J. EDGAR HOOVER, *Director, Federal Bureau of Investigation, United States Department of Justice, Washington, D. C.*

WITHIN recent months the urgent necessity of cooperation in the prosecution of war has been demonstrated over and over again on the battlefields of the Old World. Planes, guns, and ships in and of themselves cannot win, but when used together, each supporting the others, successful campaigns have been launched.

Working together to attain a goal is equally as important in times of peace when a nation is striving to make itself secure from enemy assaults both from within and without. Today our American democracy is threatened. Its future will be determined by our willingness to cooperate for national defense.

Of utmost importance in guarding the internal defenses of the Nation is sane cooperative effort, without fanfare and needless publicity. In the era of World War I there was much confusion and duplication of effort. Private groups and numerous law enforcement agencies performed national defense investigations. There was no centralized authority. In the early summer of 1939 the President of the United States, profiting by the mistakes of the past and realizing that sabotage and espionage are never local in character, selected the Federal Bureau of Investigation to head the drive on the enemies within. Later, in September of the same year, the Chief Executive requested all law enforcement officers to cooperate in this vital work by referring any facts coming to their attention indicating possible violations of our national defense statutes to the nearest office of the FBI.

The FBI Law Enforcement Officers Mobilization Plan for National Defense resulted

from the coordination of national defense activities, and through this Plan law enforcement as a whole is cooperating more closely than ever before. Regular quarterly conferences with local officers are being held throughout the country by the local FBI offices. Dozens of such meetings have been sponsored by the Albany, Buffalo, and New York City offices of the FBI in the State of New York. These have been exceptionally well attended and the local police, the sheriffs, and the state police are actively assisting in the investigation of national defense cases.

The FBI is also maintaining extremely close cooperation with officials of the Military and Naval Intelligence services. Frequent conferences are held in Washington and throughout the country between officials of the FBI and representatives of these agencies. There is a mutual exchange of information which will be of value to the other organizations.

Industry itself is now in high gear and is responding wholeheartedly to suggestions for greater protection against spies and saboteurs made by the FBI as a result of its plant survey program. The surveys were instituted in 1939 at the request of the War and Navy departments and already over 1,600 vital plants having contracts for war materials have been gone over thoroughly by trained special agents of the FBI. The sole concern is to prevent sabotage. The Federal Bureau of Investigation has no interest in legitimate labor relationships.

The citizen himself can also assist in the current emergency. Professional men, doctors, lawyers, teachers, and others occupy a unique position. They are highly trained. They

purely scientific We hope that, the experiment having been initiated, some fifty years hence no hardy survivor may sigh

“ there’s the respect
That makes calamity of so long life,
For who would bear the whips and
scorns of time,
The oppressor’s wrong, the proud man’s
contumely,

The pangs of despised love, the law’s
delay,
The insolence of office and the spurns
That patient merit of the unworthy
takes,
When he himself might his quietus
make
With a bare bodkin?”¹

¹ Hamlet, Act in sc 1

Needed Information

The State of Massachusetts is now experimenting with prepaid medical care in a manner which is new and which may furnish in time information that, in our opinion, is sorely needed. The State Legislature has passed two bills—one, sponsored by the State Medical Society, creates the usual voluntary health insurance plan approved by the A.M.A., the other permits participation only by duly licensed physicians, places control, however, under the State’s public health authorities. The latter is known as the White Cross Medical Service plan.

The first of these plans emphasizes actuarial soundness and places voluntary insurance under the control of the State Insurance Department. The second regards the quality of medical service as the primary consideration and permits those physicians who serve it to practice under any system of their choice.

After all, wide distribution of good

medical care, hospital and medical service, is the objective of all acceptable insurance plans. Everybody is agreed on this.

How it should be accomplished is another matter. Owen Wister in *The Virginian* observed that there were many religions but only one God. The same observation may be pertinent to the distribution of medical care, certainly, each of the forty-eight states has a medical problem of its own, to be solved by whatever method seems to fulfill its individual necessities. This seems to lend added weight to the Massachusetts experiment and to recommend comparable action by other states. We hope that the progressive experimentation will yield facts and figures by which the medical efficiency of both plans may be compared. Such facts and figures are badly needed in a field that still unfortunately abounds with speculation and conjecture.

Warning

On June 12 of this year “Dr F C Quitareau,” who posed as a physician under at least seven different aliases, came under investigation by the Bureau of Narcotic Control of the New York State Department of Health. He was arrested in Rochester for falsifying the narcotic records of an upstate hospital, a violation of Article XXII of the Public Health Law, according to an article published in *Health News* of July 7. He was tried by jury and sentenced, on June 23, to one year in Monroe County penitentiary.

“Dr Quitareau” had never qualified, it is stated, as a physician in the State of New York, nor had he, apparently, completed a medical course. He had been dismissed from the staffs of several hospitals and had a criminal record of five other arrests.

One reads with satisfaction of the apprehension and punishment of such an offender by the Bureau of Narcotic Control. For a year, at least, he will not falsify any more hospital records, but after that—what? His five previous arrests or his seven aliases did not prevent

UNDULANT FEVER WITH VISUAL DISTURBANCES

LEONARD W JONES, M D , and JOHN L NORRIS, M D , Rochester, New York

UNDULANT fever, known also as Malta fever, Mediterranean fever, goat fever, and brucellosis, has been epidemic for years on the Island of Malta under the name of goat fever. It was called Malta fever because of the epidemic in the Malta garrison and in the civilian population of the island from 1898 to 1904 when there were 2,229 cases with 77 deaths. It was called Mediterranean fever because of its prevalence along the shores of the Mediterranean. Goat fever naturally came from the fact that in Malta and the Mediterranean the disease was spread through the agency of goat's milk, and some 10 to 15 per cent of the goats on the island of Malta were found to have the micrococcus in their milk. It was given the name of brucellosis because of the work of the British Army surgeon, Sir David Bruce, who in 1886 isolated an organism, the micrococcus melitensis, from the spleen and blood of goats and of human beings and definitely proved the animal etiology of the disease. The name undulant fever is descriptive of the wavelike character of a victim's temperature curve.

The headaches, neuralgias, arthritic effusions, and tendency to chronicity of this animal-borne disease are all well known and freely described and discussed in textbooks and journals. We have yet to find a textbook in which anything is said as to eye symptoms or eye complications in association with undulant fever, although such phenomena and possibilities are beginning to appear in the journals. Some 5 cases of undulant fever with papilledema and cases of iritis in brucellosis patients have been reported. But on the whole the literature on undulant fever in its relation to eye pathology would seem to show that there was little or no connection between the two. Experiments on guinea pigs and white mice in which these animals were injected with *Brucella abortus* failed to produce any pathologic lesions in some forty eyes examined.

There is an eye disease occurring in horses—a recurring uveitis, a periodic ophthalmia bearing the popular name of "moon blindness." This disease is described by Burky, Thompson, and Zepp, and these authors suggest that this uveitis may be a manifestation of brucellosis. These authors were also able

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 7, 1940.

to produce in rabbits a recurring indokeratitis resembling "moon blindness" by injecting the anterior chamber of rabbit's eyes with a culture of *Br abortus*.

In September, 1938, in investigating the defective vision and the appearance of multiple scotomas in a factory employee, our only clue to the etiology was that the girl was positive to both *Br abortus* and *Brucella melitensis*. Subsequent study showed that these peculiar multiple scotomas were not really multiple at all but that a more careful technic showed them to lie in the course of a curved path through the visual field and that these curves corresponded more or less to the retinal tree. In other words, it was possible to outline blind areas between these isolated spots and join them all to make a sinuous scotoma.

We set out then, with the exceptionally efficient aid and cooperation of a nurse keenly interested in ophthalmology, to make field studies of many employees whose symptoms did not fit into regular orthodox pigeonholes and also to take fields on employees whose visual symptoms could not be explained on the usual diagnoses and hypotheses. Both types of employees were then checked by skin and agglutination tests with *Br abortus*.

As a result of these studies we feel that there is relationship between undulant fever and the eye, that this relationship shows itself chiefly by a marked widening of the normal angioscotoma, that it may show itself by a central scotoma that interferes with vision, and that at least 1 case of uveitis and 1 case of conjunctivitis were apparently due to undulant fever.

It may be of importance here to state what we mean by "widening of the normal angioscotoma," and to do this we will have to condense freely from *Clinical Scotometry* by Evans.

The retinal arteries and veins as they come out of, and return into, the cup of the optic nerve form a picture known as the retinal tree. You can see that picture in your own eye silhouetted in space, if you hold up the light of an electric ophthalmoscope against the globe through the closed lid.

By using small enough targets and great care in fixation and by having a cooperative patient and a painstaking patient field taker,

should be the last to be carried away by hysteria. Individuals of this type can be of inestimable service as listening posts and by reporting immediately to the FBI any facts indicating possible infractions of our national defense statutes. Vigilante action is repugnant to our sense of justice and fair play. The citizen should not gossip, evaluate, or investigate but should report the facts at once

and clear his mind of the matter. The three FBI offices in New York State are open twenty-four hours a day and are located at 707 National Savings Bank Building, Albany, 400 United States Court House, Buffalo, and 607 United States Court House, Foley Square, New York City. The FBI is your organization. Appropriate action will be taken on all information furnished.

"SOCIALISM FOR BEGINNERS"

"Some are large,
Some are small,
Some are short,
Some are tall,
Some are thin,
Some are fat,
We must chango
All of that!"¹

"AMERICAN DOCTORS FOR BRITAIN"

"Sir I am much interested in this subject now before the profession from an experience during the last war, when I occupied the position of chairman of the Recruiting Medical Boards for Cumberland at Carlisle, where thousands of men were examined. I have no hesitation in expressing the view that the present arrangements are superior to 1914-1918, and if they were effected to the full there should be little need for the emergency call for 1,000 American doctors at this time. But it is not so, for although a large number of available British doctors have already registered in the ordinary course comparatively few have been posted to date.

"During the recruiting period of the last war applications for posts on Medical Boards were received from qualified men hailing from several other countries, and a number were accepted, but temperamental variation and habitude barred the way to good cooperation and harmony, acute friction resulted with consequent resignation, with the result that the whole clinical system extant suffered acutely. I would like to be informed why so many English doctors, quite dispensable for service, under the age of 30 have not been called up and are enjoying seclusion in their own practices. I am satisfied that if the committees in authority for absorbing all the available medical man-power were exhaustively conducted, there would be little need for the emergency call to the Western Hemisphere, initiating an anomalous position. During the last war medical man-power was reduced to an absolute minimum, and only a fraction of the medical community was left to carry on medical practices—in fact, a dangerous position was reached. At the present time, however, the general health of the nation is good, and the vital intelligence of the people is such that this should be maintained for the remainder of the war—I am, etc."

C W GRAHAM, J P

*Ex-President of the Border Counties Branch
B.M.A.*

—Brit M J, 834 (May 31) 1941

Silloth, May 13

were as follows. This patient was an unmarried, attractive girl of 21. She was healthy in appearance except that she was underweight. She gave a history of frequent headaches, considerable postnasal discharge, and some blurring of vision. Because of this blurring she had not been doing her work properly.

On September 16, 1938, when her history was taken and a physical examination was made (Fig 1), she said she smoked about ten cigarettes a day and drank an occasional glass of beer or a cocktail. She had no domestic, financial, or love worries to distract her mind from her work, and as far as she knew she was in good health.

FIG 2 Tangent screen study of Case 2 Vision 6/6 All fields 17 5/1,000 No fundus pathology

FIG 1 Tangent field study of Case 1 made on September 16, 1938 Left eye vision 6/7—corrected to 6/7+ by -0.50 cyl. X 180 Eye grounds—normal. Form., 4/1,000, colors, 3/1,000, ring scotoma, 4/1,000, central scotoma, 2/1,000, illumination, 6 5 foot candles

Her pulse was 70 Her blood pressure was 120/70 Her temperature chart, kept for two weeks, showed a fluctuation between 96 and 99 F, with a high point of 101.2 F and a low of 95.4 F, and had the undulations characteristic of brucellosis.

An examination of her head and neck, sinuses, glands, heart, and chest showed all to be normal.

Her blood showed a hemoglobin of 95 percent, a red cell count of 4,850,000, and a white cell count of 6,200 Her blood Wassermann was negative and a glucose tolerance test eliminated diabetes. There was agglutination with Br abortus (1-1,280) and with Br melitensis (1-640) Her reflexes were hypersensitive, which seemed to exclude multiple sclerosis.

Could undulant fever explain her headaches and visual disturbances? She came to the plant on April 1, 1936 Her vision then was

6/6, her temperature, pulse, and respirations were, respectively 99 F, 80, and 20 She said she had been hot and feverish at intervals during the last six months.

Her progress under sulfanilamide treatment has not been startling Her headaches are less and her vision became 6/6— with her glasses. On October 30, 1939, her angioscotomas were still definitely enlarged.

Case 2—V C was referred to the Eye Clinic because she complained of blurring vision and with it vertical headache, pain in the knees, and malaise.

Her eyes showed 6/6 vision in each eye without correction. There was no need for glasses, no fundus pathology, no nystagmus, and no diplopia. Her fields showed scotomas of the type that we have come to know as widening of the normal angioscotomas, and a typical one, that of the right eye on October 31, 1938, is here charted (Fig 2).

The curved pericentral scotoma is a widening of the normal angioscotoma. The scotomatous islands are probably errors in field-taking technique. This girl is temperamental to a degree that makes it difficult for the technician to take a proper field. These islands could probably be joined by curved lines to form a typical angioscotoma.

Looking back on this girl's health record with the company, we find that on admission as an employee on January 26, 1933, she had an oral temperature of 99 F and her vision in each eye was 6/4-1 She lives on a farm with her mother and their milk comes from one cow. This cow is positive to undulant fever. Serologic tests on the girl have given various reactions, some negative and some mild and not con-

it is possible to outline the shadow cast by these vessels on the eye fields just as one outlines the scotoma or blind spot formed by the optic nerve. Evans dislikes the term "shadow cast by these vessels" because the scotoma is greater than the size of the vessel and would seem to be induced by a lymph stasis around the vessel. These projections of the retinal tree on a field chart are known as "angioscotomas."

Normally, the largest trunks form a scotoma of 1 degree to $1\frac{1}{2}$ degrees, and 1 degree at 1 meter or 1,000 millimeters casts a shadow or scotoma of 17.4 mm in width. We take then a scotoma of 17.4 mm at 1 meter and in the path of the projected retinal tree to be part of a normal angioscotoma. Anything greater than that, or rather greater than $1\frac{1}{2}$ degrees or 26.3 mm., is a variation from normal or a "widening of the normal angioscotoma."

Angioscotomas are subject to change without notice from change of posture, compression, light, menstruation, nasal cavity manipulation, cervical sympathetics stimulation, and other causes. Their chief point of distinction and identification is that they follow the course of the retinal tree.

In the routine work of our Eye Clinic and particularly for this special work in marking out angioscotomas, we tried out the ordinary perimeter, the Peter's small hand scotometer, the Bausch and Lomb stereocampimeter, and the instrument of the American Optical Company which uses mirrors instead of prisms to produce stereoscopic effect. It has been our experience that defects that fail to show with other instruments are revealed by the large Bausch and Lomb tangent screen with its special overhead projected illumination. We have come to the conclusion that the tangent screen best serves our purpose, and this screen is being used almost exclusively.

We have studied some 111 cases with symptoms more or less suggestive of undulant fever. In order to bring this paper somewhere within readable length, we have selected for presentation only 6 cases from the 111 studied. We show, for the same reason, only the field of one eye where both eyes showed similar field defects. Most of our cases have had repeated field checks over many weeks and months, and 2 have had over a year of study. While we have their charts on file, we have not loaded up this thesis with their reproduction.

So, too, we have presented in detail only our first case (M T). With the others we

have presented the case history in as brief a form as possible. But all cases have had complete physical examinations.

We now present our case studies and statistical findings.

Case Reports

Case 1—On September 12, 1938, M T, a young woman, was sent to our Eye Clinic because she had been missing defects in a manufactured product which other inspectors could detect. Her vision was slightly below normal with or without glasses, and her error of refraction was so small that, at her age, glasses were not considered necessary. There was a slight horizontal nystagmus, but the interior of her eyes showed a normal healthy fundus and no explanation for her blurring vision.

Having a retrobulbar neuritis in our minds, a result of multiple sclerosis or some toxic disturbance, we had field studies taken on a Bausch and Lomb tangent screen. The right eye showed a small absolute scotoma (central) for white and blue, and the left eye showed also an absolute central scotoma for white and colors with a large winding scotoma in the midtemporal field.

Since the normal projected shadow cast by a retinal vessel (temporary and disputed definition for an angioscotoma) is only $1\frac{1}{2}$ degrees wide and this curved scotoma measures considerably more than that, it seemed logical for us to regard this ring scotoma not as an angioscotoma but as something more sinister. However, a perusal of Evan's interesting book on angioscotometry, *Clinical Scotometry*, and a personal communication from Dr. John Evans lead us to believe that what we had here was a lymph extension or stasis from the retinal vessel or that we had charted two retinal vessels as one.

A medical check-up proved definitely that she did not have multiple sclerosis, that she was and apparently had been running a low-grade fever for some time, and that she was positive (agglutination test) to both the Br abortus and Br melitensis.

Looking into her history we found that she lived in a nearby village with a large Italian population and that goats, while not so abundant as on the Island of Malta, were very much in evidence. However, she denies that she has ever drunk goat's milk, and the family milk supply comes from various dairies. She is the only member of the family affected. However, she visits an aunt at a village some 60 miles away where the milk supply is raw milk, but it is not known whether the cows have undulant fever.

Subsequent field studies showed variations in the size and shape of these angioscotomas, but on the last examination, February 13, 1939, the ring scotoma was still present, the central scotoma had disappeared, and her vision with correction was 6/6—

The clinical history and physical examination

FIG 6 Tangent field study of Case 5 made on December 23, 1938 Right eye vision 6/7—, not improved by any lens Angioscotoma charted with 4/1,000

On April 1, 1939, she was admitted to the Genesee Hospital with a diagnosis of undulant fever. She was given sulfanilamide with no improvement, but after intravenous typhoid in April, 1939, she showed marked progress.

A subsequent field study on April 17, 1939, one week after leaving hospital, showed a marked reduction in size of angioscotomas (Fig 5).

On November 11, 1939, the angioscotomas were still normal in spite of the fact that she had had a cold. This time she had no malaise, aches, or pains.

Her only history of possible contact was on one occasion when she drank raw milk.

Case 5—G. S., a girl aged 21, came to the Medical Department on December 19, 1938, complaining of headache. Her previous medical history was of frequent colds, sore throat, and abdominal discomfort. She was sent to the Eye Clinic on December 21, 1938, and an examination showed no eye pathology but a strongly suspicious angioscotomatous enlargement (Fig 6).

On March 8, 1939, she was given Br. melitensis vaccine and developed a markedly positive reaction. On March 23, 1939, she was positive on agglutination to 1-80 Br. abortus and to 1-80 Br. melitensis.

This girl was given 160 Gm. of sulfanilamide over a period of four days and showed no improvement.

On July 20 tests were positive with Br. abortus (1-40) and Br. melitensis (1-20).

Case 6—E. F. was a woman, aged 38. This case is particularly interesting in that she came to the Eye Clinic on July 3, 1939, with a blood-shot eye of four days' duration. An examina-

FIG 7 Tangent screen field of Case 6 made on November 22, 1939 Right eye

FIG 8 Tangent field study of Case 6 made on November 22, 1939 Left eye

tion showed a vision of 6/48 without glasses and 6/18 with glasses in the right eye, with a steamy cornea. The pupil was contracted and active, and the iris was dilated evenly and without adhesions. The details of the fundus could be indistinctly seen because of the cloudy media. A diagnosis of uveitis was made.

A hunt for a focus of infection in tonsils (removed), teeth, sinuses, and the like failed to show any reason for the uveitis. A Wassermann test was negative.

Two days later all eye symptoms had increased, and there were marked deposits on Descemet's membrane.

FIG 3 Tangent screen field of Case 3 made on December 21, 1938 Right eye vision 6/6-4 Angioscotoma plotted with 4/1,000, central scotoma, with 2/200

FIG 5 Tangent screen study of Case 4 made on April 7, 1939 Left eye

FIG 4 Tangent screen study of Case 4 made on January 12, 1939 Left eye vision 6/12 corrected to 6/7- Angioscotoma charted with 4/1,000 target, central scotoma, with 1/1,000

vincing, but eventually she was proved positive to undulant fever by a skin test

A temperature chart kept for one week showed variations between 97.6 and 99.2 F Her chief complaints, in addition to those mentioned, were fatigue, insomnia, and sore throat

Small absolute scotomas (paracentral) developed in the right eye in March, 1939, and in the left eye in September, 1939 It is difficult to explain why, with absolute paracentral scotoma, this girl had no loss of vision, unless it was that

the absolute center of the macula remained unaffected

She has been treated with sulfanilamide and has shown periods of improvement and periods of retrogression At time of writing she is improved, but her progress under treatment has not been convincing

Case 3—W W, complained of fatigue, malaise, and some headache He had a postnasal discharge but otherwise an essentially negative physical examination

On October 17, 1938, his vision in each eye was 6/6-3, he had normal fundi, but his field studies showed certain bizarre scotomas that rightly or wrongly we had come to associate with undulant fever (Fig 3) To our disappointment an agglutination test proved negative

We were naturally suspicious of undulant fever because this man kept goats and occasionally drank their milk He left the plant because he felt too sick to work On his return to the factory a skin test was positive to both Br abortus and Br melitensis

Case 4—R. S. was a young woman with joint pains and joint swellings Her case had been diagnosed by her family physician as rheumatoid arthritis She had had a tonsillectomy in April, 1938, to remove a possible focus of infection. She complained of her hack bothering her and of frequent colds

On January 12, 1939, she was sent to the Eye Clinic Her right eye had vision of 6/9 improved to 6/6- by her correction There was no fundus pathology The left eye similarly had vision of 6/12 corrected to 6/7- (Fig 4)

Her fields of vision showed the scotomas of angioscotomatous type, and a skin test for undulant fever was mildly positive

BLOOD PRESSURE STUDIES IN THE AGED

ISIDORE MILLER, M D, New York City

"GERIATRICS has been a neglected field of medicine. At present the mortality at advanced ages is considerably more than necessary, owing to neglect of special study in the anatomy and physiology of senescence."¹ Geriatrics will assume a greater importance with the years as the changes in the age distribution of the population become more marked. At present 260 of every 1,000 people in the United States are 40 years of age and over. It is estimated that by 1960, 36 per cent of the population will be between 40 and 65 years of age. In 1930 there were 6,500,000 people in this country 65 years of age and over, by 1980, it is estimated there will be 22,000,000.²

The problem of what constitutes the limits of normal blood pressure is of interest to all who examine patients. Most studies of the blood pressure have reported figures for the younger adult groups. Only recently has the factor of old age come into prominence.

Life insurance underwriters have prepared tables for normal blood pressure averages of white male groups.³ These tables show that the blood pressure rises from a systolic of 120 and a diastolic of 79 at the age of 20 to a systolic of 138 and a diastolic of 89 at the age of 65. With advancing years the average normal systolic pressure increases more rapidly than the diastolic pressure but much more slowly than the age. For a general rule, permitting variations of 10 mm. in the systolic pressure and 5 mm. in the diastolic, the normal range is 110 to 148 systolic and 70 to 95 diastolic, approaching the upper limits in the older age groups.

Alvarez,⁴ in his examinations of the freshmen students at the University of California (6,000 men and 8,934 women), found that the blood pressure did not increase with age, in men the average pressure dropped from the age of 17 to 21, then remained the same to 50, in women there was a drop from the age of 17 to 25, then it rose rapidly after 25 and extremely rapidly after 40. He found that 45 per cent of the men and 12 per cent of the women had systolic pressures over 130, 22 per cent of the men and 2 per cent of the women had systolic pressures over 140.

Diehl and Sutherland⁵ studied the blood

pressures of 5,122 men entering the University of Minnesota in 1922, 1923, and 1924. In 1922, 16.2 per cent had a systolic pressure of 140 and over. In 1923 and 1924 the men were given a rest period before examination and only 9 per cent had a pressure of 140 and over. They felt that nervousness and excitement were important factors in producing transient hypertension in young people.

Alvarez and Stanley⁶ studied the blood pressures of 6,000 prisoners and 400 guards. They found that the percentage of men with pressures over 140 in the ages between 20 and 40 remained almost constant, and they suggested that those with hypertension at 40 had had it also at 20. Five per cent of white prisoners of all ages between 15 and 39 had hypertension. Of 58 prisoners between 60 and 84 years, 37 or 64 per cent had pressures under 139 mm. They stated that a pressure of 115 mm. was just as normal and a pressure of 140 was just as abnormal in an old man as in a young man.

Bowes⁷ studied the blood pressures of 50 men and 100 women with ages ranging from 65 to 94 years. The systolic pressure of the men rose from 145 in the 60- to 65-year group to 163 in the 80- to 84-year group. The women showed a similar rise from 154 to 183. Both men and women showed a marked fall in systolic pressure in the 90- to 94-year group. The diastolic pressures varied from 81 to 91 in the men and from 80 to 90 in the women, the lower figures were present in the 90- to 94-year group. The pulse pressure varied in the men from 63 to 80 and in the women from 53 to 98. The pulse pressure, too, showed a drop in the 90- to 94-year group. Of the 150 patients, 22 had systolic pressures over 200, 28 had diastolic pressures over 100, and 30 had pulse pressures over 100.

Lewis⁸ studied the blood pressures of 100 men, 20 in each decade from 40 to 89 years, he included 1 man of 90 and 1 of 101. These studies were made in the basal state. The systolic pressure rose continually after 40, the greatest rise was seen after 65. The systolic pressure was 116 at 40 to 44 years, 124 at 60 to 64 years, 158 at 85 to 89 years. The 2 men over 90 had lower pressures. The average diastolic pressures varied slightly in succeeding decades. The pulse pressures were greater at the higher age groups since the

From the New York City Farm Colony, Staten Island, New York.

On July 6, 1939, she was given Br abortus, and on July 7 both the agglutination test and the skin test were reported negative. On July 12 a tuberculin test was negative.

On July 17 it was noted that the erythema around the undulant skin test remained at 1 cm. diameter after twelve days. This had been done with Br abortus 1-80 dilution and Br melitensis (1-40).

On November 22, 1939, the eye had practically recovered from the attack of uveitis and the tangent fields were taken in both eyes, with enlargement of the angioscotomas as noted on the charts (Figs 7 and 8). She was given neoprontosil.

Here we have a girl with a uveitis whose origin we were unable to discover, unless it was due to undulant fever. In proof of this theory we have positive skin and agglutination tests and, what is significant to us, marked widening of the normal angioscotomas.

Summary and Conclusions

1 Since September 16, 1938, we have studied some 111 cases by means of tangent screen fields. Some of these were routine eye examinations with visual abnormalities not explained by intraocular or extraocular pathology, error of refraction, or central nervous system disease. Some were examined because of physical complaints. Some were done as part of an eye study of the employees whose work brings them in contact with various chemicals.

2 Of these 111 cases, 92 or 81.41 per cent showed widening of the normal shadows of the retinal tree or angioscotomas.

3 Of those that showed increased angioscotomas, 75 or 81.5 per cent showed positive

skin reactions indicative of undulant fever.

4. Of the 19 that showed normal angioscotomas, 3 showed positive skin tests or 15.7 per cent.

5 Field studies were also done on a small group of patients suffering from various afflictions, from sinusitis to appendicitis, to determine whether an enlargement of the angioscotomas was merely due to a congestion of the vessels of the head such as might follow or accompany any febrile reaction. Our results would not seem to substantiate this theory.

6 Stated conservatively, we believe that there is a definite relationship between angioscotomas and undulant fever. We believe that this relationship usually takes the form of an enlargement of the normal angioscotoma and occasionally is accompanied by small central scotoma and disturbances in vision.

7 Whether these enlargements of the normal angioscotomas are definitely diagnostic of undulant fever is doubtful or improbable. They may turn out to have the same relative value as an increase in the white cell count in mastoiditis or appendicitis. But whether they are of diagnostic value or not, they are interesting phenomena accompanying undulant fever and will bear further study.*

* **AUTHORS' NOTE.** Since the preparation of this paper we have changed our plan of attack in treating suspected brucellosis. We now use brucellosis vaccine in preference to sulfanilamide. While the results on the whole have been better and while we have had some startling cures, some of our cures have had relapses and slipped back to the original blurring vision for which they sought relief. But this, after all, is characteristic of brucellosis behavior.

CONNECTICUT STATE MEDICAL SOCIETY TO HOLD SEVENTEENTH CLINICAL CONGRESS

The Connecticut State Medical Society will hold its seventeenth annual Clinical Congress in the Sterling Law Buildings of Yale University at New Haven, on Tuesday, Wednesday, and Thursday, September 16, 17, and 18.

Among the guest speakers from outside of Connecticut will be Drs. Sara Jordan, Paul A. Younge, Oscar F. Cox, James L. Poppen, Gilbert E. Haggert, Samuel A. Levine, Frank D. Lathrop, Grantley W. Taylor, and Frank H. Lahey, of Boston; Emil Novak, of Baltimore; Robert H. Kennedy, Ernst P. Boas, David C. Bull, Burrill B. Crohn, Thomas Francis, Jr., and Jerome T. Webster, of New York City; E. Jefferson Browder and Matthew Walzer, of Brooklyn; Y. D. Koskoff, of Pittsburgh; George St. J. Perrott, of Bethesda, Maryland; and Irvine H. Page, of Indianapolis. In addition to these speakers, many Connecticut physicians will present papers.

Tuesday morning's session will be devoted to the main to gynecologic subjects, Tuesday afternoon's, to the effects of trauma, and Wednesday morning's, to cardiovascular disease. The remaining sessions will present a varied and well-rounded program of interest to all physicians.

Members of the Congress may enroll in a special course in Traumatic Surgery to be given under the direction of Dr. Samuel C. Harvey of the Yale School of Medicine. This course will begin at the time of the Congress and continue at weekly intervals until completed.

Any physician may register for the Congress. The registration fee for the Congress is \$2.00 and for the special course in Traumatic Surgery is \$1.00 additional. Detailed information and registration cards may be obtained by writing to the Connecticut Clinical Congress, 258 Church Street, New Haven, Connecticut.

140 and 20 per cent had a pressure of 200 and over. Fifty-one per cent had a diastolic pressure under 90 and 16 per cent had a pressure of 110 and over. Twenty-six per cent had a pulse pressure under 60 and 35 per cent had a pressure of 90 and over.

This study has included the effects of age and sex on the blood pressure. There are other factors that play a part, but these would act equally on the 65-year-old and the 100-year-old person. The effect of increased weight on the blood pressure was not studied. The patients, as a group, were of normal or slightly below normal weight in relation to their height.

Sex does play an important role in the picture. In the older age groups the women had higher average pressures than the men (except the 85- to 89-year group). Alvarez and Zimmerman¹¹ thought that these women had a heredity tendency to hypertension which became manifest only with the loss of ovarian secretion. Up to 40 years, Symonds³ found that men had a systolic pressure 1 to 2 mm. more than women, after the age of 40 the pressure of women rose much above that of men.

Fishberg¹² defined essential hypertension as a constitutional, familial, and hereditary disease (probably diseases) which has been aptly termed constitutional hypertension.

As accessory factors he included emotional and psychic strains, overeating, and obesity. A family history was unknown or indefinite in most of these patients. Worry, fear, grief, and mental work play little part now in their lives. The aging process itself usually brings a peace of mind and mental relaxation.

Fineberg¹³ found that patients with elevated systolic pressure and a relatively low diastolic pressure formed a definite group characterized clinically by their relatively advanced age. These cases ran a benign and prolonged course. He included in this group cases with systolic pressures over 150 mm. and diastolic pressures below 90 mm. The high systolic pressure was caused by vasoconstriction of the peripheral vascular bed, the low diastolic pressure was due to atherosclerosis of the aorta and larger vessels. Wiggers¹⁴ expressed the opinion that, in hypertension, constriction affected the entire arterial tree. In the smaller vessels this produced increased peripheral resistance, in the larger vessels the capacity and extensibility were reduced. Diminished elasticity of the aorta and the larger arterial branches in atherosclerosis plays an important part in producing an increase in the pulse pressure. Table 1 shows that systolic hypertension is the common type in the older age groups. Among the men, from the age of 75 years and

TABLE 1—EFFECT OF AGE ON THE AVERAGE BLOOD PRESSURE

90-94				158	75	83

systolic pressures rose more than the diastolic pressures. He stated that the general trend of the systolic pressure was a rise and was directly related to age.

Willius,⁹ in a study of the blood pressure in 700 persons 75 years of age and over, found a systolic pressure over 140 in 74 per cent, a diastolic pressure over 90 in 40 per cent, and a pulse pressure over 60 in 69 per cent. His study was conducted on people who had come to the Mayo Clinic because of the presence of some pathology. In a further study of the cardiovascular system in old age, Willius and Smith¹⁰ reported their results in 381 patients, 70 years and over. A systolic pressure over 140 was present in 64 per cent, a diastolic pressure over 90 in 37 per cent, a pulse pressure over 60 in 60 per cent. These figures were lower than in the previous study because a younger age group (70 to 74 years) was included. Willius stated that his figures showed a tendency for hypertension to occur in old age.

The blood pressure studies at the New York City Farm Colony were done on 853 men and 128 women. The readings were taken during routine physical examinations that took place daily between 9:00 and 12:00 A. M. The pressures were taken with a mercury manometer by the auscultatory method, with the patients in a sitting position. The diastolic reading was taken at the end of the loudest sound and not at the total disappearance of sound. Each patient had a physical examination every six months. They were accustomed to the examination and to the taking of the blood pressure, fear and excitement due to possible adverse physical findings were present in only a few of the patients.

Concerning the nationality of these patients, about 45 per cent were natives of the United States, 20 per cent, of Ireland, 13 per cent, of Germany, 5 per cent, of Italy, with scattered small percentages from the rest of Europe, Japan, Canada, Cuba, and the Virgin Islands. These men were predominantly nonskilled workers in their youth, in this institution,

if they were physically able, they were asked to do two hours of light work daily. They lead a simple life, have few worries, have their meals at regular hours, and can rest in their beds any time they wish. Many of these men have no families or have lost contact with their families. These patients do not have the emotional upsets concerned with "making a living." The storms and strifes of life leave most of them unperturbed. Alvarez and Stanley⁸ in their study of prisoners and prison guards found a lower blood pressure in the prisoners. They believed that the "basal" state of the prisoners (no responsibilities) was the logical explanation.

Table 1 shows the effect of age upon the average blood pressure. In men the systolic pressure rose from 132 in the 50- to 54-year group to 157 in the 85- to 89-year group. The diastolic pressure varied only slightly with age (from 84 to 87 mm). The pulse pressure rose from 46 to 71. In women the systolic pressure rose from 155 in the 50- to 54-year group to 176 in the 80- to 84-year group, this was followed by a fall. The diastolic pressure varied only slightly (84 to 94 mm) from 54 to 84 years, after 85 years there was a fall. The pulse pressure rose from 61 to 82. With increasing age a fairly constant rise in the systolic and pulse pressures occurred in the men. In women the results were not so clear cut but, if the 65- to 69-year group is excluded, the tendency for the rise in systolic and pulse pressures is present up to 84 years. Systolic, diastolic, and pulse pressures were higher in the women than in the men at all age groups except the 85- to 89-year group.

Table 2 shows the variations in blood pressure with age. Forty-six per cent of the men had a systolic pressure under 140 and 5 per cent had a pressure of 200 and over. Seventy-five per cent had a diastolic pressure under 90 and 5 per cent had a pressure of 110 and over. Forty-two per cent had a pulse pressure under 60 and 15 per cent had a pressure of 90 and over. Twenty-five per cent of the women had a systolic pressure under

systolic pressures rose more than the diastolic pressures. He stated that the general trend of the systolic pressure was a rise and was directly related to age.

Willius,⁹ in a study of the blood pressure in 700 persons 75 years of age and over, found a systolic pressure over 140 in 74 per cent, a diastolic pressure over 90 in 40 per cent, and a pulse pressure over 60 in 69 per cent. His study was conducted on people who had come to the Mayo Clinic because of the presence of some pathology. In a further study of the cardiovascular system in old age, Willius and Smith¹⁰ reported their results in 381 patients, 70 years and over. A systolic pressure over 140 was present in 64 per cent, a diastolic pressure over 90 in 37 per cent, a pulse pressure over 60 in 60 per cent. These figures were lower than in the previous study because a younger age group (70 to 74 years) was included. Willius stated that his figures showed a tendency for hypertension to occur in old age.

The blood pressure studies at the New York City Farm Colony were done on 853 men and 128 women. The readings were taken during routine physical examinations that took place daily between 9:00 and 12:00 A.M. The pressures were taken with a mercury manometer by the auscultatory method, with the patients in a sitting position. The diastolic reading was taken at the end of the loudest sound and not at the total disappearance of sound. Each patient had a physical examination every six months. They were accustomed to the examination and to the taking of the blood pressure, fear and excitement due to possible adverse physical findings were present in only a few of the patients.

Concerning the nationality of these patients, about 45 per cent were natives of the United States, 20 per cent, of Ireland, 13 per cent, of Germany, 5 per cent, of Italy, with scattered small percentages from the rest of Europe, Japan, Canada, Cuba, and the Virgin Islands. These men were predominantly non-skilled workers in their youth, in this institution,

if they were physically able, they were asked to do two hours of light work daily. They lead a simple life, have few worries, have their meals at regular hours, and can rest in their beds any time they wish. Many of these men have no families or have lost contact with their families. These patients do not have the emotional upsets concerned with "making a living." The storms and strifes of life leave most of them unperturbed. Alvarez and Stanley⁶ in their study of prisoners and prison guards found a lower blood pressure in the prisoners. They believed that the "basal" state of the prisoners (no responsibilities) was the logical explanation.

Table 1 shows the effect of age upon the average blood pressure. In men the systolic pressure rose from 132 in the 50- to 54-year group to 157 in the 85- to 89-year group. The diastolic pressure varied only slightly with age (from 84 to 87 mm.). The pulse pressure rose from 46 to 71. In women the systolic pressure rose from 155 in the 50- to 54-year group to 176 in the 80- to 84-year group, this was followed by a fall. The diastolic pressure varied only slightly (84 to 94 mm.) from 54 to 84 years, after 85 years there was a fall. The pulse pressure rose from 61 to 82. With increasing age a fairly constant rise in the systolic and pulse pressures occurred in the men. In women the results were not so clear cut but, if the 65- to 69-year group is excluded, the tendency for the rise in systolic and pulse pressures is present up to 84 years. Systolic, diastolic, and pulse pressures were higher in the women than in the men at all age groups except the 85- to 89-year group.

Table 2 shows the variations in blood pressure with age. Forty-six per cent of the men had a systolic pressure under 140 and 5 per cent had a pressure of 200 and over. Seventy-five per cent had a diastolic pressure under 90 and 5 per cent had a pressure of 110 and over. Forty-two per cent had a pulse pressure under 60 and 15 per cent had a pressure of 90 and over. Twenty-five per cent of the women had a systolic pressure under

determination Of these, 35 (7 per cent) had a blood glucose of over 120 mg Fourteen (2.8 per cent) had blood glucose of 150 mg and over The average blood pressure was increased in diabetes (160 systolic pressure as compared to 147 systolic pressure in the non-diabetic patients) Of the 35 patients with a blood glucose of over 120 mg, 5 (14 per cent) had a blood pressure of 200 mm or over

To determine the effects of syphilis on the blood pressure, a study was made of the blood pressures of 500 patients who had had Wassermann tests Of these, 40 (8 per cent) had a 3 or 4 plus Wassermann reaction The average systolic pressure in this group was 148.7 mm This compared closely to the average systolic pressure of 147 mm in the negative Wassermann group

Conclusions

1 With changes in the age distribution of population, geriatrics will assume greater importance Further studies in physiologic old age are needed to give us standards that can be used for comparison

2 In men the average systolic pressure rose from 132 mm at 50 to 54 years of age to 157 mm at 85 to 89 years of age The diastolic pressure varied only slightly with increasing age The pulse pressure rose from 46 mm to 71 mm

3 In women the systolic pressure rose from 155 at 50 to 54 years of age to 176 at 80 to 84 years of age The diastolic pressure varied only slightly The pulse pressure rose from 61 to 82

4 Systolic, diastolic, and pulse pressures were higher in the women than in the men at all age groups except in the 85- to 89-year group

5 Systolic hypertension with a relatively low diastolic pressure was a common finding in the older age groups

6 A predisposition of particular blood groups to hypertension has not been demonstrated

7 Hypertension, per se, had no effect on the erythrocyte count and hemoglobin

8 The vital capacity was normal for all blood pressure groups except for the group with a systolic pressure of 200 and over

9 Diabetes mellitus was associated with an increase in systolic blood pressure

10 A positive Wassermann reaction had no effect on the blood pressure

ODD KIND OF PASTIML

A new use for the stethoscope is reported by the regular London, England, correspondent of the *Journal of the American Medical Association* in the March 15 issue He says

"In gratitude for his work in removing delayed action bombs which fell in the east end of London, Capt Robert Davies, who is in command of the bomb disposal squad, has been presented with a stethoscope by the resident staff of one of the hospitals He has frequently borrowed a stethoscope from the hospital in order to listen to the ticking of delayed action bombs before removing them"

HE HURT HIS FINGER

Vladimir Horowitz, pianist, whose concerts occasionally have been broadcast, has been forced to cancel all engagements for the remainder of the year His three consulting physicians released the following statement

"We have under our care Mr Vladimir Horowitz who is convalescing from a traumatic tenosynovitis of the flexor digitorum sublimis and profundus muscle at the metacarpophalangeal joint"

Horowitz has an injured finger

—Radio Column, Pittsburgh Post-Gazette, quoted in the Illinois Medical Journal

% 200 and over	17	4	4	5
Diastolic press., mm				
% over 90	25	25	21	26

up, the average systolic pressure was above 150 and the average diastolic pressure was below 90. Among the women the average systolic pressure was above 150 at all age groups (except the 85- to 89-year group), but the average diastolic pressure was slightly higher than 90 in half of the age groups.

Robinson and Brucer¹⁵ differentiate average and normal blood pressure. They found that the average systolic pressure rose with age but that normal blood pressure did not. To obtain their normal readings they excluded those with a systolic pressure over 140 and a diastolic pressure over 90 (13.3 per cent of their cases). Just as many old men as young men had low blood pressures. In their opinion the normal range of systolic pressure is from 90 to 120 mm., of diastolic pressure, from 60 to 80 mm. Pressures higher than these are a sign of incipient hypertension, and it is these prehypertensive and hypertensive pressures that rise with age.

In Table 2 it can be noted that if the patients with systolic pressures of 140 and over were excluded, 50 per cent of the men in the seventh decade and over 60 per cent of the men in the eighth and ninth decades would be affected. There is a decrease in the percentage of men with average systolic pressures under 140 with age (from 68 per cent in the 50- to 54-year group to 33 per cent in the 85- to 89-year group). In their older age groups, Robinson and Brucer's figures show a similar decrease with age in the percentage of men with average systolic pressures under 140

(from 75 per cent at 55- to 59-years to 38 per cent at 75- to 79-years).

To determine whether the percentage distribution of blood groups in old age differed from that present in the general population, blood group determinations were made on 500 people 65 years of age and over. The figures are shown in Table 3. In reviewing the literature, a paper on this subject by Graves¹⁶ was noted in which he reported a percentage increase of 13.9 in Group O, and 1.7 in Group A in old age as compared to his findings in college men. Levine¹⁷ stated that it was not likely that the blood group incidence varied with age since there was no increased mortality in any of the blood groups. Further studies will have to be made on the older age groups before any conclusion can be drawn.

In Table 4 the blood groups have been separated into various blood pressure levels. Groups A and O, in which 86 per cent of the patients are included, show an almost similar incidence in the percentage of hypotensive, normal, and hypertensive cases. Group AB has a larger percentage of cases with systolic pressure over 200, but only 18 cases of Group AB are present. With this one exception, the figures do not show that any blood group is predisposed to hypertension. Wiechmann and Paal¹⁸ found a relative predominance of Groups III and IV in hypertension.

Miller¹⁹ has reported the effects of variations in blood pressure on the hemoglobin and erythrocytes in old age. The patients were divided into four groups according to their blood pressure. The 120- to 140-mm group had the highest red blood cell count (4,500,000), and the hypotensive group had the lowest (4,370,000). The 140- to 160-mm group had the highest hemoglobin average (14.4 Gm.), while the 160-mm and over group had the lowest (14.2 Gm.). The differences in the red blood cell count and in the amount of hemoglobin in the various groups were slight.

In a study of vital capacity in old age²⁰ the effect of variations in blood pressure were noted. The average vital capacity of the group as a whole was 2,780 cc., 70 per cent of normal. The vital capacity was within average limits for all blood pressure groups except the one with a systolic pressure of 200 and over. This group gave an average vital capacity of 2,400 cc., 60 per cent of normal.

To determine the effect of diabetes on blood pressure, a study was made of the blood pressures of 500 patients over 60 years of age who had had a morning blood glucose

It does not, however, solve the problem of the minor or trivial injury. Should antitoxin be given or withheld in this type of injury? That question is still more perplexing and unsolvable. We all know that it is not practical to give tetanus antitoxin to every child with a trivial injury. We are not called to see most of the trivial injuries, even if we were, the chief objection is the high incidence of uncomfortable serum sickness, not to mention the always present danger of immediate anaphylaxis to horse serum, precluding further injections. Besides, the whole population of children might become so sensitized to horse serum by repeated injections that when it was really urgent to give other horse serums, as in diphtheria or meningitis, it would be dangerous to do so. There is a bovine type of tetanus antitoxin available, but it is quite expensive for routine use.

Most of these objections can now be overcome by

(2) *Active Immunity with Tetanus Toxoid*—Recently, it has been shown by an increasing number of investigators that active immunization against tetanus by means of tetanus toxoid is not only possible but extremely practical.

The principle is the same as in the universally employed active immunization against diphtheria with diphtheria toxoid. It is a well-established immunologic fact that when a specific antigen (in this case toxoid) is injected specific antibodies (antitoxin, etc.) develop and, also, that after a certain interval, if the antigen is again injected, the response of developing antibodies is much accelerated in time and amount. One of the essential differences, however, between the response in diphtheria and tetanus active immunization is that in the former the antitoxic content of the blood usually remains at a sufficiently high protective level for many years, while in the latter, after a shorter period of time, the antitoxic level in the blood often falls below the protective level of 0.1 unit of antitoxin per cubic centimeter of blood. However, it rapidly reaches the protective level again after another injection of the toxoid. Another difference is that there is no simple clinical test, such as the Schick test, to determine the degree of immunity to tetanus. There are apparently no children naturally immune to tetanus toxin. Tetanus antitoxin titrations on numerous children have never revealed any antitoxin present in their blood before immunization.

Now, what does all this mean when trans-

lated into practical immunization against tetanus?

1 Alum-precipitated tetanus toxoid is given subcutaneously or intramuscularly in 0.5 or 1 cc doses, depending on the product used.

2 Two doses are given two to three months apart.

3 The antitoxic titer of the blood is usually, but not invariably, raised well above the protective level (0.1 unit of antitoxin per cubic centimeter of blood) against tetanus infection within a few months or sooner after the second dose. Even when the interval is as long as nine months between these doses extremely high titers of antitoxin are produced.

4. This high titer usually persists for three or more months after the second dose—at times up to two years—and then may fall to less than the protective level.

5 Another dose of 0.5 to 1 cc of alum-precipitated toxoid, called the "boosting" or "stimulating" dose, given at any later time after the original two doses when exposure to possible tetanus has occurred, will within three days, in all instances, raise the antitoxin content of the blood to an effective protective level again, even much higher than after the second dose. Thus, adequate protection is insured. This again may gradually fall below the protective level in three to six months, although not necessarily so. Another boosting dose at any time will again raise it sufficiently within three days. In other words, this basal immunity, which responds so readily to a secondary stimulus, is probably lifelong.

Even though the antitoxin resulting from the primary stimulation may fall to a low level after a few months, a secondary or stimulating dose produces a much more rapid, greater, and prolonged antibody response and corresponding immunity than that obtained by the two primary injections. Boosting doses may be given to those children previously actively immunized when the physician is consulted for an injury.

6 Theoretically, and this is of utmost importance, even without this artificial boosting dose the stimulus of the tetanus toxin generated in a fresh wound should act as a natural boosting dose in a person whose basal immune mechanism is set to combat tetanus by previous active immunization. This individual should show a rapid immunity response to the stimulation from the production of tetanus toxin in the wound, and so the child with the

TETANUS—ITS PREVENTION AND TREATMENT

JOSEPH K. CALVIN, M D , Chicago

BEFORE attempting to outline the modern methods of preventing and treating tetanus, allow me to say a few words about the present conception of its pathogenesis

Pathogenesis

Tetanus bacilli infecting a local wound and remaining localized at this site generate tetanus exotoxin, which is absorbed into the circulation and is distributed throughout the body by the blood stream. It becomes fixed by the anterior horn cells of the central nervous system, resulting in reflex convulsive activity (intermittent muscular spasms). It also exerts a peripheral action in the region of the motor end plates of the muscles, causing generalized persistent muscular rigidity.

Incidence

Although the disease is relatively rare considering the widespread prevalence of the bacilli, any abrasive wound, no matter how trivial, may conceivably result in the dreaded malady. It has recently been conclusively demonstrated that the tetanus bacillus is widely distributed in street dust, even in the present horseless day. In practically every case of childhood tetanus seen at the Cook County Hospital the wound is trivial, such as those resulting from a thorn or nail, a stone bruise, a small splinter, a blister, a small abrasion, laceration or crush, a slight burn, a prick of a needle, etc. Superficial healing is usually already present, and oftentimes the wound cannot be found at all. This has also been the experience of other observers. Children, especially boys, are continually receiving trivial injuries. The organism may be on the soiled skin or clothing, even if not on the puncturing body, and may be driven into the wound at the time of the puncture or laceration. Consequently, one of the most distressing points in connection with tetanus is the possibility of its appearing when least expected, and more disquieting still is the knowledge that the largest number of cases follow the most trivial injuries. There is no way of foretelling which will develop tetanus.

Prophylaxis

Tetanus can now be prevented by two methods

(1) *Passive Immunity—Tetanus Antitoxin*—As we all know, 1,500 to 5,000 units of tetanus antitoxin injected subcutaneously within a few hours after an injury will prevent the development of tetanus. Fifteen hundred units will apparently protect a child with a minor wound. If there is a considerable interval between the time of injury and the administration of antitoxin or if there is a severe injury such as a compound fracture or crushing dirty wound, doses of 5,000 to 10,000 units are indicated. In these severe injuries it is advisable to combine gas bacillus antitoxin with the tetanus antitoxin. This passive immunity lasts only about seven to fourteen days. Consequently, if the wound does not appear to be clean and healing, the injection should be repeated every ten days, provided no serum sickness is present, since then the danger arises of producing an Arthus reaction (local gangrene). The repeated injections should never be given near the site of a previous injection for the same reason. If a suspicious wound must be reopened, even after months, i.e., for the extraction of a foreign body, another prophylactic dose must be given because of the possibility of the surgical procedure's stirring up old tetanus spores.

Adequate surgical care of the wound is extremely important so that the wound will have healed by the time the passive immunity disappears. The customary surgical measures should be employed. It is especially important to extract foreign bodies if possible.

With such an adequate means of prevention we might wonder why tetanus still occurs. The prophylactic dose would commonly be administered in certain types of injury. This is correct as far as it goes. Every physician exercising ordinary diligence and skill would administer the antitoxin in obviously dangerous wounds, such as those due to gun powder (Fourth of July injuries, etc.), auto accidents in which the wound usually is contaminated with soil and manure, compound fractures, severe puncture wounds, severe or infected burns, dirty lacerations, etc. Because this is commonly done, we at the Cook County Hospital have seldom seen tetanus follow these severer types of injuries.

1. Read by invitation at the Annual Meeting of the Medical Society of the State of New York, New York City May 8, 1940

Attending physician, Sarah Morris Children's Hospital of Michael Reese Hospital

It does not, however, solve the problem of the minor or trivial injury. Should antitoxin be given or withheld in this type of injury? That question is still more perplexing and unsolvable. We all know that it is not practical to give tetanus antitoxin to every child with a trivial injury. We are not called to see most of the trivial injuries, even if we were, the chief objection is the high incidence of uncomfortable serum sickness, not to mention the always present danger of immediate anaphylaxis to horse serum, precluding further injections. Besides, the whole population of children might become so sensitized to horse serum by repeated injections that when it was really urgent to give other horse serums, as in diphtheria or meningitis, it would be dangerous to do so. There is a bovine type of tetanus antitoxin available, but it is quite expensive for routine use.

Most of these objections can now be overcome by

(2) *Active Immunity with Tetanus Toxoid*—Recently, it has been shown by an increasing number of investigators that active immunization against tetanus by means of tetanus toxoid is not only possible but extremely practical.

The principle is the same as in the universally employed active immunization against diphtheria with diphtheria toxoid. It is a well-established immunologic fact that when a specific antigen (in this case toxoid) is injected specific antibodies (antitoxin, etc.) develop and, also, that after a certain interval, if the antigen is again injected, the response of developing antibodies is much accelerated in time and amount. One of the essential differences, however, between the response in diphtheria and tetanus active immunization is that in the former the antitoxic content of the blood usually remains at a sufficiently high protective level for many years, while in the latter, after a shorter period of time, the antitoxic level in the blood often falls below the protective level of 0.1 unit of antitoxin per cubic centimeter of blood. However, it rapidly reaches the protective level again after another injection of the toxoid. Another difference is that there is no simple clinical test, such as the Schick test, to determine the degree of immunity to tetanus. There are apparently no children naturally immune to tetanus toxin. Tetanus antitoxin titrations on numerous children have never revealed any antitoxin present in their blood before immunization.

Now, what does all this mean when trans-

lated into practical immunization against tetanus?

1 Alum-precipitated tetanus toxoid is given subcutaneously or intramuscularly in 0.5 or 1 cc doses, depending on the product used.

2 Two doses are given two to three months apart.

3 The antitoxic titer of the blood is usually, but not invariably, raised well above the protective level (0.1 unit of antitoxin per cubic centimeter of blood) against tetanus infection within a few months or sooner after the second dose. Even when the interval is as long as nine months between these doses extremely high titers of antitoxin are produced.

4. This high titer usually persists for three or more months after the second dose—at times up to two years—and then may fall to less than the protective level.

5 Another dose of 0.5 to 1 cc of alum-precipitated toxoid, called the "boosting" or "stimulating" dose, given at any later time after the original two doses when exposure to possible tetanus has occurred, will within three days, in all instances, raise the antitoxin content of the blood to an effective protective level again, even much higher than after the second dose. Thus, adequate protection is insured. This again may gradually fall below the protective level in three to six months, although not necessarily so. Another boosting dose at any time will again raise it sufficiently within three days. In other words, this basal immunity, which responds so readily to a secondary stimulus, is probably life-long.

Even though the antitoxin resulting from the primary stimulation may fall to a low level after a few months, a secondary or stimulating dose produces a much more rapid, greater, and prolonged antibody response and corresponding immunity than that obtained by the two primary injections. Boosting doses may be given to those children previously actively immunized when the physician is consulted for an injury.

6 Theoretically, and this is of utmost importance, even without this artificial boosting dose the stimulus of the tetanus toxin generated in a fresh wound should act as a natural boosting dose in a person whose basal immune mechanism is set to combat tetanus by previous active immunization. This individual should show a rapid immunity response to the stimulation from the production of tetanus toxin in the wound, and so the child with the

injury too slight to consult a physician would probably also be protected

7 The use of the combined alum-precipitated toxoids of tetanus and diphtheria, given at the same time, does not interfere with the specific immunity response of either. The immunity to each disease developed by the two specific toxoids given together is no less than that developed by each specific toxoid separately. The dose is in the same volume (1 cc). Thus, we can offer the added protection against tetanus without any additional effort or injection.

8 The reactions to alum-precipitated tetanus toxoid when given alone are few and, on the whole, have been mild. There is usually some transient local tenderness. Because of the presence of potassium aluminum sulfate (alum) in the preparation, absorption is delayed. An indurated nodule persists at the site of injection for quite a long time when given subcutaneously, but it disappears within forty-eight hours when given intramuscularly. No serum sickness or hyperallergic sensitivity develops as a rule. It can be safely used in allergic individuals or those sensitive to animal serums. There is little danger in repeated injections. My co-workers and I have given about two thousand injections of the tetanus toxoid to children and, even though some of the subjects previously or at the time had eczema, asthma, hay fever, etc., only 3 children developed a mild general reaction (mild urticaria) from the injections. However, very rarely the first injection of toxoid can so sensitize an individual that a fairly severe allergic reaction may occur with subsequent injections. When the diphtheria toxoid is combined, the reactions in children under the age of 6 years are as a rule also slight. In older children there is more marked reaction because of the increased sensitivity to the diphtheria bacillus protein in older individuals, which apparently does not apply to the tetanus bacillus protein. Consequently, it is wise in older children to give 0.2 cc of the combined tetanus and diphtheria toxoid as a test dose.

9 Although it had previously been stated that combined active-passive immunization is not feasible, the two types of immunization being incompatible with each other, it has recently been conclusively demonstrated that combined immunization of one injection of serum (tetanus antitoxin) and a simultaneous injection of tetanus toxoid, followed by repeated injections of tetanus toxoid in the usual manner, is able to superimpose uninterruptedly active immunity on passive immun-

ity. This insures a permanent antitoxic immunity against tetanus and is the best prophylaxis against tetanus for the nonvaccinated wounded patient. In short, children treated by serovaccination have the same antitoxic response to a subsequent reinforcing dose of toxoid injected after several months or later as patients who have been vaccinated only with the toxoid.

10 For extensive injuries such as would require gas bacillus antitoxin prophylaxis, it is best to give tetanus antitoxin also (the two are commercially available combined in one vial), even though the child was previously actively immunized. In this type of severe injury the incubation period might be under three days, and it may require up to three days to raise the antitoxin titer sufficiently with the boosting dose of toxoid. In any case, if the second injection of toxoid has not as yet been given, a prophylactic dose of tetanus antitoxin should be given under those conditions in which the antitoxin is ordinarily used. Otherwise, a stimulating dose of toxoid is given.

11 Because the repeated injections of toxoid raise the question of occasional (rare) sensitization with its local and systemic reactions, a special tetanus toxoid, topagen, has recently been used intranasally. By using it intranasally for two or three successive days, every six months, the protective level of antitoxin in the blood is said to be maintained at an adequate level in advance of an injury, providing the original two doses have been given by injection. This method is so new that it requires further confirmation.

Active Treatment

Every case of tetanus is a grave emergency, and no time should be lost in instituting treatment regardless of how mild the case may appear. Death is usually due to convulsive asphyxia with tonic fixation of the respiratory muscles. Late deaths may result from pneumonia.

The actual therapy can be divided into (1) sedative therapy, (2) specific therapy with tetanus antitoxin, (3) nursing and symptomatic care, and (4) surgical treatment of the wound.

(1) *Sedative Therapy*—The purpose of sedative therapy is to prevent or control convulsions and in that way prevent death from asphyxia or exhaustion. It is indicated before attempting to carry out any other procedures.

The ideal antispasmodic should rapidly re-

lax the patient enough to allay the convulsions and rigidity without complete loss of consciousness or collapse from the drug. If possible, the cough and pharyngeal reflexes should not be abolished. Avertin fluid (tribromethanol amylene hydrate) meets these requirements. It is easily administered rectally in children, beginning with 25 mg per kilogram of body weight in the average case and repeating with 10 to 15 mg per kilogram every fifteen minutes until moderate relaxation is effected. Usually, it is not necessary to give more than 50 mg per kilogram to gain the necessary relaxation. If severe asphyxial convulsions are already in evidence, the initial dose should be increased to 50 mg per kilogram or, if spasms are absent, it may be reduced to 15 mg. The relaxing effect lasts anywhere from one to six hours or longer; then the above treatment must be repeated for days or weeks until the child remains fairly well relaxed without sedation. If adequate amounts are employed, muscular relaxation ensues within five to ten minutes. The patient should be maintained within the dim border of consciousness, but the onset of restlessness and increasing rigidity calls for more sedation to forestall the onset of an asphyxial convulsion. The advantages of avertin are especially (1) the ease of fractional administration without pain and (2) its rapid and potent action compared with other drugs given rectally. Other investigators have had equal success with seconal or amytal.

(2) *Specific Therapy*.—As mentioned previously, tetanus toxin reaches the nerve tissues through the circulation after being absorbed into the capillaries from the local site of wound infection. If these nerve tissues have already fixed a lethal dose of toxin before serum is used, it will have no value. However, in any given case of tetanus we cannot know whether a full lethal dose has already been fixed. The timely injection of a large amount of antitetanic serum neutralizes the newly formed circulating toxin (elaborated in the wound), preventing it from becoming fixed in the susceptible tissues in lethal amounts. Only that fraction of toxin that has already been fixed by the specifically reactive tissues is decisive for life or death. Any additional circulating toxin may be neutralized and rendered harmless. Neither sedatives nor serum is self-sufficient but are complementary to each other, sedatives to combat the results of toxin already bound to nerve tissue (convulsions and rigidity) and serum to forestall further toxin fixation.

Antitoxin administered *intravenously* will reach and neutralize the circulating toxin most rapidly, and the time element is of the greatest importance. The intraspinal route has been discarded and condemned as dangerous and inefficient.

A single massive dose of 50,000 units is given intravenously. It must be diluted in at least 500 cc of normal saline and given slowly by the gravity drip method to avoid reactions. Another 50,000 units is given intramuscularly for more prolonged absorption. Bio-assay has shown that this amount affords a liberal excess of antitoxin in the blood stream, even a month or more later, capable of preventing further spread of toxin even weeks after the danger period of tetanus has passed. It may be wise to give epinephrine hypodermically some minutes before beginning the intravenous administrations, since a serum reaction might precipitate a fatal asphyxial tetanus convulsion. Also the patient should be tested for unusual sensitivity to horse serum before giving it intravenously.

Recently, it has been advocated to give, in addition to the antitoxin, 2 cc of tetanus toxoid intramuscularly, and then 4 cc and up to 6 cc are repeated at intervals of five or six days. It has been demonstrated that active immunization due to the toxoid follows without interruption the passive immunization due to serotherapy. This is a certain means of avoiding relapses and recurrences.

Lack of improvement in the patient is no indication to continue indefinitely with serum therapy, for once all available circulating toxin not bound by nerve tissue is neutralized and an excess of antitoxin is present, which certainly should occur within twenty-four hours or less, further administration would have no further value. Sedatives and supportive measures must then be relied upon to control convulsions and maintain life until the central nervous system has had an opportunity to recover. It can do this completely providing a lethal dose of toxin has not already been fixed before antitoxin is administered. Occasionally, but uncommonly, after serum administration, signs of brain edema appear. These can be relieved by $MgSO_4$ intramuscularly and 50 per cent glucose intravenously.

(3) *Nursing and Symptomatic Care*.—A nurse, if possible one trained in the care of tetanus patients, must be in constant attendance on a child with tetanus if adequate sedative therapy is to be attained. She must recognize the indications for the repetition of

sedatives and have the equipment always ready for their immediate administration. She should be able to administer avertin herself if necessary. One of the advantages of this drug is that a nurse can be easily taught to administer it rectally.

Nourishment must be given to prevent starvation and exhaustion. It is frequently possible with sedatives to relax the trismus sufficiently so that the patient can take plenty of soft high carbohydrate foods, small curd milk, and fluids by mouth with little difficulty. No chewing should be attempted, food being administered best by bottle and nipple or medicine dropper. The best time for feeding is when the patient awakens by himself and is still sufficiently relaxed, or just as he is going under the influence of the sedative, rather than arousing him especially to take food. In severe cases when the child is unconscious most of the time because of the necessary large doses of sedatives, dextrose and saline can be given intravenously by continuous drip. Subcutaneous administration of fluids is avoided because the pain may cause reflex convulsions. Nasal catheter feedings are dangerous in unconscious children because of the danger of vomiting and asphyxia.

Blood transfusions are useful when sepsis or pneumonia complicate the tetanus or in the late convalescent stages in markedly debilitated or anemic children.

The position of the child should be changed at the times the sedatives are repeated to reduce the incidence of pneumonia—a frequent complication.

The emergency procedure for asphyxia is to give artificial respiration while sedatives are being administered to relax the respiratory spasm.

If excessive mucus accumulates in the nasopharynx, it may be controlled by small doses of atropine. Aspiration by suction is usually contraindicated unless it can be done without exciting the child.

Abdominal distention or urinary retention must be watched for and relieved by enemas and catheterization, but adequate sedatives should be given before disturbing the child for any such treatment.

(4) *Surgical Treatment of the Wound*—As mentioned above, in our experience in most cases of tetanus in children the wound is slight and oftentimes healed, or there is no wound to be found at all. It is questionable whether the wound should be disturbed if it is healing or healed, since the prompt injection of adequate amounts of antitoxin intra-

venously soon neutralizes all the circulating toxin and the toxin being formed locally for some time to come, this may be combined with repeated toxoid injections to superimpose an active immunity on the passive immunity without interruption. Never is a case of tetanus *pér se* a surgical emergency, and no surgical procedure should be attempted until the child is thoroughly relaxed under sedative or general anesthesia, as the excitement might easily produce a fatal asphyxial spasm. Amputation or disfiguring operations are never justified in the surgical treatment of uncomplicated tetanus. In general, *only such surgery as to be recommended as would be required if the patient did not have tetanus*.

Discussion

Dr Francis J. Gustina, Buffalo, New York—Dr Calvin has given us a splendid paper on the present status of the prevention and treatment of tetanus. The first essential in treatment is to give a large dose of tetanus antitoxin intravenously as soon as the condition is suspected. Our scheme is to give 100,000 units at once, diluted with about three times or more of its volume with sterile 5 per cent glucose solution. Every case should be considered an immediate emergency as far as administering the antitoxin is concerned, for we have no way of telling clinically whether the patient may have had sufficient toxin fixed to kill him by the time we see him. The intravenous route must be used to get the neutralizing antitoxin to the affected tissues as soon as possible. One must think of tetanus whenever a patient presents symptoms suggesting the disease, and particularly is this true when local tetanus occurs. If treatment can be instituted prior to the onset of tactile reflex symptoms, recovery is more probable.

The use of combined diphtheria-tetanus toxoid is a real advance in preventive medicine. As Dr Calvin has brought out in the paper, it is an easy and effective way to secure more general protection against this disease which may arise from the most trivial type of wound. That this will prove to be the case in humans even though a new injection of toxoid is not given after an infected wound—provided the person has been previously immunized—seems to be suggested by the experience of the French who have recently reported on the elimination of tetanus in army units, the horses included, after such prophylactic immunization has been carried out. The only disadvantage of using the combined toxoid for active immunization is the possibility of local and occasionally general reactions. In our experience three local reactions of severity have been noted, in these cases an inflamed circumscribed cystic mass developed which appeared to be an abscess. All were left alone and were completely absorbed in varying time—

from two to five weeks. It was a great temptation to do something, but in view of the fact that these were undoubtedly sterile abscesses or liquefied areas it was decided to leave them alone, and this turned out to be quite satisfactory. The incidence of such reactions reported to date has been so low that it should not be a deterrent to the use of this valuable measure.

With respect to general reactions, they have not been observed by us. Our material is chiefly limited to infants, and this may account for the lack of any systemic reactions.

Dr J L McCartney, Philadelphia—Dr Calvin has presented an excellent survey of the prevention and treatment of tetanus and has pointed out that toxoid immunization is now beyond the experimental stage.

This is quite obviously so, as the injection of toxoid is now accepted by the English, French,

and Italian armies. After a test period at the United States Naval Academy at Annapolis on about 3,000 cadets, it is now being accepted by the U S Navy. A report of this work was presented at the recent meeting of the American College of Physicians.

Dr Calvin has pointed out that, after two initial injections of toxoid, a third, boosting or stimulating, dose gives the individual full protection. This dose may be given at regular intervals or immediately after the individual has been injured, and protection is assured in three to five days. A recent article by Gold, appearing in the May issue of the *American Journal of Surgery*, brings out the fact that this booster dose is just as effective if given in the nose as when injected and that the instillation of the toxoid in the nose prevents the reactions that sometimes occur when the toxoid is injected. The toxoid for intranasal instillation is known as tetanus "topagen."

TWISTING THE DRAFT REJECTION FIGURES

Propagandists as well as hars figure, observes the *New York Medical Week*, so it was perhaps to have been expected that interested groups would seize upon the medical statistics of the Selective Service System as an argument for state medicine. Actually there is nothing in these figures either to occasion alarm for the nation's health or to suggest that political control of medical care would better it.

Comparisons between current draft statistics and those of the last war are bound to be erroneous because the standards of physical and mental selection are much more rigid today. Warned by the cost of pensions and veterans' medical services since 1918, the government is seeking to bar potential as well as obvious misfits from the army now in training.

Many physicians believe that some of the reasons for deferment are inconsequential from the practical point of view and that men are being rejected who could prove useful in occupations requiring limited physical activity. This is, of course, for the Army to decide, but it is safe to say that many of those refused as physically unfit are reasonably healthy by ordinary civilian standards and capable of fulfilling the social and economic demands of normal life.

There has, it is true, been a substantial percentage of rejections because of physical deficiencies that cannot be dismissed as unimportant, but few of these can be attributed primarily to lack of opportunities for suitable medical care.

State medicine would not prevent the rheumatic hearts which have kept a considerable number of young men out of training, for, so far, neither the cause nor cure of rheumatic fever is known. Neither would it banish many congenital deformities and traumatic defects for which reparative procedures have not yet been devised.

Rejections for insufficient teeth, defective eyesight, and underweight are greatly to be deplored, because in many cases the disqualifying fault could have been prevented. Here the remedy is public education rather than state-controlled therapy. More stress on proper nutrition, hygienic use of the eyes and other organs, and also early recourse to medical and dental aid would do far more to improve the general level of health than the subjection of medicine to a politically dominated bureaucracy.

On the whole, it may be said that the American youth of today compares favorably in all essential physical respects with his predecessors. If the percentage of military rejections seems excessive, it is because health standards are higher and diagnostic procedures more accurate than in the past. As Dr Roger I. Lee, president-elect of the American College of Physicians, recently declared, there has been overemphasis on the relation of draft medical statistics to the general health of the nation. "A steady fall in death rates is an indication that the American people today are healthier than ever before."

PNEUMONIA IS CONTAGIOUS

Additional evidence that pneumonia is a contagious disease and that all patients with it should be strictly isolated, even during convalescence, is presented in the *Journal of the American Medical Association* for June 7 by Drs Sydney S Gellis and A Grime Mitchell, Cincinnati.

"Nine instances of cross-infection with type I pneumococcus occurred in November and December of 1939 during a period of two weeks in the pediatric service of the Cincinnati General Hospital," the two physicians say. "All the children, with one exception, were between the ages of 2 and 3 years."

ALLERGIC REACTIONS IN THE ABDOMEN

T WOOD CLARKE, M D , Utica, New York

USUALLY when one thinks of the allergic diseases the mind turns to asthma, hay fever, eczema, or urticaria. This is because the earliest recognition of the condition was in these more common manifestations of the allergic reaction.

To confine one's thoughts on allergy to the respiratory and cutaneous systems is an error. The reaction may occur in any organ in the body. According to its type and location many varied symptom complexes may appear. Previously, I have presented the subject of allergic manifestations in the central nervous system.¹ Here I will discuss those in the abdominal organs.²

The allergic reaction may manifest itself in one of four ways—hyperemia, edema, glandular hypersecretion, or smooth muscle contraction. Two or more of these may occur simultaneously. If the condition persists, the resistance of the tissues may become reduced, and secondary infection or chronic proliferation results. This is commonly seen in chronic sinusitis, aphthous stomatitis, or nasal polyp.

Allergic reactions of the gastric mucous membrane may be either acute, chronic, or recurrent. The acute attacks are usually caused by direct contact. When a person takes a food to which he is markedly allergic there may be a prompt urticaria at all points of contact. The lips may swell tremendously, the esophagus may become edematous, and the swelling of the gastric mucous membrane may cause violent vomiting, with or without abdominal pain.

A number of years ago a baby, aged 13 months, was referred to me by Dr Girard, then of Lyons Falls, who suspected intestinal obstruction. The child had been vomiting for four days. The bowels had moved the first day but not since. The child was in collapse, semiconscious. Except for the lack of blood in the stools the picture was typical of intussusception. A barium enema, however, filled the colon completely. The symptoms were so suspicious that the barium enema was repeated. Again the findings were negative. The vomiting continued. As the baby appeared to be starving, 1 ounce of skimmed milk was given. In a few minutes a urticaria appeared over the entire body. This sug-

gested that the vomiting was a manifestation of cow's milk allergy. Skin tests gave a reaction to cow's milk casein and lactalbumin and to goat's milk. Milk was discontinued. Glucose enemas were given and a milk-free diet was prescribed. Vomiting stopped promptly, the baby became conscious, took its food ravenously, and during the week it remained in the hospital gained $1\frac{1}{2}$ pound in weight. Such violent vomiting occurring during the first few weeks of life may be difficult to differentiate from pylorospasm. Some authors claim that true pylorospasm may have an allergic etiology.³

The chronic manifestations of gastric allergy may be caused by direct contact or as a part of a systemic allergic reaction. The chronic hyperemia or edema of the stomach wall may cause bad breath, coated tongue, anorexia, flatulence, eructation of gas, vague, more or less severe pains, or indefinite abdominal discomforts—all the symptoms popularly called dyspepsia.

When the edema has lasted some time, ulceration may follow. During the last few years a number of authors⁴ have reported cases indistinguishable from peptic or duodenal ulcers which have proved to be the direct result of gastric allergy. In these cases the offending protein has usually been egg, wheat, or milk. As soon as the causative protein has been identified and removed from the diet the symptoms have disappeared, and x-ray examinations have shown rapid healing of the ulcer. Feedings of the offending protein causes prompt return of the symptoms. It is important to recognize this relation of allergy to gastric ulcer, especially in cases that do not show prompt recovery when placed on the Sippy diet. Where the ulceration is due to a milk allergy the condition is aggravated by the milk in the Sippy diet. Withdrawal of milk will cause prompt permanent recovery.

The recurrent manifestations of gastric allergy are best exemplified by the so-called cyclic vomiting of children, a condition frequently of allergic origin.⁵

Intestinal symptoms due to the allergic reaction may also be either acute, chronic, or recurrent. A violent diarrhea, sometimes bloody, may follow a few hours after the ingestion of some food to which the patient is sensitized.⁶ On the other hand, the sudden

edema of the intestinal wall may be so great as to cause a temporary occlusion of the bowel with symptoms of intestinal obstruction

A few years ago I was called in to see a child whom I had been treating for asthma. She had been taken ill suddenly with violent vomiting, intense abdominal cramps, and collapse. On examining the abdomen a round movable mass the size of a small orange was discovered to the left of the navel. The father, a physician, assured me that the mass had not been there the day before. Suspecting that the mass was due to impacted feces, I recommended an intestinal cleansing. The next day the mass had disappeared. A month later, however, the attack recurred when there was no suggestion of an underlying constipation. This happened several times, until the father appreciated that the attacks occurred whenever the child was given an egg. On an egg-free diet the attacks failed to recur.

In other cases the attacks of acute abdominal pain, vomiting, and rigidity may so closely simulate acute appendicitis⁷ or cholecystitis as to indicate immediate operation. On opening the abdomen no acute inflammation is found. The appendix or the wall of the gallbladder may be swollen and edematous but not reddened, or there may be a localized edema of a portion of the intestine or of the parietal peritoneum. If the appendix is removed, it will show eosinophilic infiltration. In such cases, even after the appendix has been removed, the attacks will usually recur to the mortification of the surgeon. The recurrent attacks of edema of the appendix due to allergic attacks may result in a true infective appendicitis.⁸ Henoch's purpura, which combines purpuric eruptions on the skin with acute abdominal pain, is now recognized as a manifestation of allergy.⁹

When the allergic reaction in the small intestine is chronic or recurrent the picture is that of chronic intestinal indigestion, loss of appetite, recurring pains, and tenderness located first at one point then at another, sometimes constipation and at other times diarrhea. The sufferer from this type of allergy lives a life of unhappiness and discomfort, travels from physician to physician, either submits to numerous operations that give no relief or is assured that there is nothing wrong or that the symptoms are the result of that useful hook on which we hang the hat of our ignorance—a functional neurosis.

A few months ago such a case was sent to me. She was a married woman, aged 27.

Her family history included a grandfather who suffered from repeated headaches and a cousin who had asthma. In childhood she had vomiting attacks about once a month. At 16 she began having severe headaches, associated with vomiting, about once a week. These had continued up to the present. She had also suffered for years from attacks of abdominal pain located in various parts of the abdomen. She had hives if she ate strawberries. She was constipated. Two years ago her condition was diagnosed as chronic appendicitis and the appendix was removed. No improvement resulted. This spring her physician told her that her trouble was in the gallbladder and that it must be removed. She went to Syracuse for the operation where careful examinations by a surgeon and a roentgenologist failed to demonstrate any evidence of gallbladder disease. She was then referred to Dr. Hitchcock, an internist. Dr. Hitchcock, in consideration of her history of migraine and urticaria, suspected that the case might be one of intestinal allergy and referred her to me.

On the first day's testing she gave a suspicious reaction to wheat by the scratch test. This was confirmed later by a strong reaction to the intradermal test. Wheat was removed from her diet and in two days her abdominal pains had disappeared. During the past six months she has had no headaches, vomiting, or abdominal pains, she gained many pounds in weight and says that for the first time in ten years she feels quite well. Whereas she has always lived on a most carefully selected and restricted diet, she now eats anything she wishes provided it contains no wheat.

When the reaction is confined to the colon a different picture appears. Here we usually get three of the characteristic allergic reactions: edema of the mucosa, spasm of the muscle wall, and hypersecretion of the mucous glands. These three combined give the classic picture of mucous colitis. It is now nearly twenty years since Vaughan¹⁰ called attention to the fact that mucous colitis was a manifestation of food allergy, an opinion confirmed by many allergists since that time.

Recent roentgenologic studies of mucous colitis have conclusively demonstrated spasticity of the colon when the offending protein is given either by mouth or incorporated in a barium enema.¹¹

Today all allergists agree that most cases of mucous colitis are allergic in origin, and some insist that all are. When the cause, usually wheat, is discovered and eliminated from the

diet the symptoms disappear promptly. If the colonic edema persists, the resistance of the mucous membrane is lowered and an ulcerative colitis¹² or colonic polypi¹³ may result. In such cases the treatment of the ulcerative colitis or polypi is greatly simplified if the underlying allergic factor is discovered and removed from the diet.

In 1940 Necheles and his associates¹⁴ at the Michael Reese Hospital have reported a series of 6 cases of gallbladder allergy in which careful x-ray examination demonstrated a hyperactivity of the gallbladder wall associated with gallbladder colic when the food to which the patient was sensitive was administered.

Although eighteen years have passed since Duke¹⁵ first called attention to the fact that the allergic reaction could occur in the urinary system, few urologists even give the matter a thought. It is well known that acute nephritis and hematuria may occur as an accompaniment of serum sickness, proving that anaphylactic changes can occur in the kidneys.¹⁶

In the bladder, too, allergy may play an important role in the production of symptoms. All students of allergy report cases in which bladder pain is the result of allergic reactions in that organ. Edema combined with muscular contraction of the bladder wall may result in excruciating pain and tenesmus. If the allergic condition is allowed to progress, polypi or ulceration may result. When secondary infection occurs the presence of pus in the urine may cloud the picture.

Two such cases have come under my observation lately. The first was a young married woman, aged 22. In her family history her father has had two attacks of urticaria and her great uncle had asthma. Her sister has perennial hay fever. As a child she had a slight eczema at the bend of the elbows. At the age of 12 a mild attack of appendicitis was followed by an appendectomy. During her convalescence from the operation she had an attack of pyelitis lasting several weeks.

Ever since then she has suffered at frequent intervals from severe pains in her bladder, considered to be the result of cystitis. Usually her urine was clear but at times there would be a few pus cells. All through her life in boarding school and college she would be obliged to stay in bed at frequent intervals and apply heat over the bladder region. At times the pain was severe. No form of local treatment had any effect on the attacks. In February 1940, when consulting Dr. Sears in Syracuse,

the possibility of her symptoms being due to bladder allergy was discussed, and a complete allergic study was recommended. Though the scratch tests were negative to all foods, intradermal tests gave definite reactions to wheat and chocolate. These were removed from her diet. During the next seventeen months the patient, who previously rarely went a week without an attack, has been entirely free from pain except, when on one or two occasions, social duties necessitated her eating some food containing wheat.

The second case is a woman, aged 50. For several years at her summer home she has had attacks diagnosed as cystitis. This fall on returning to Utica, though she was complaining of severe bladder pains, her urine was found to be either free of pus or to contain only an occasional leukocyte. Treatments, first with mandelic acid and then with urotropin, failed to give more than temporary relief. An allergic study was made, and this patient also gave reactions to intradermal tests with chocolate and wheat. She had herself been suspicious of chocolate. Since removal of these from her diet she has had no more pains in her bladder except once after eating a little chocolate.

In the sphere of the gynecologist, cases have been reported of dysmenorrhea, menorrhagia,¹⁷ and irritation and excoriation of the vulva¹⁸ due to food allergy being completely relieved by an allergic study with resultant dietary reform.

The most important factor in the diagnosis of abdominal allergy is an appreciation that such a condition exists and that it can simulate any known acute or chronic abdominal lesion. In making a diagnosis of any so-called surgical belly, the possibility of allergy must be kept in mind. When the abdominal pain is associated with an attack of asthma or a crop of hives, allergy is at once suggested. If there is a family or past history of other allergic manifestations, allergy must be seriously considered. It frequently happens, however, that the allergic manifestations occur in the abdomen and nowhere else in patients with no suggestive history. In such cases the diagnosis is not easy and one must be guarded in making it.

To refrain from operating on a patient with acute appendicitis, intussusception, or perforated gastric ulcer in order to make an allergic study requiring several days would be criminal. Even in these acute cases, however, we have one diagnostic help. If the case is allergic, a hypodermic injection of adrenalin

will usually cause prompt relief of the symptoms. In the true surgical abdomen such relief will not occur. In all such acute cases, unless relieved by adrenalin, it is safer to operate first. Then if the symptoms recur, think of allergy.

It is in the patients with chronic abdominal pain that the allergic study should be made, especially in those patients in whom an exact diagnosis cannot be made by the ordinary means. In patients with chronic symptoms suggesting indigestion, peptic ulcer, cholecystitis, appendicitis, colitis, and cystitis the allergic examinations are of most value. They should not, however, be undertaken until careful physical examination and complete x-rays and laboratory tests have failed to show any organic lesion. If an expected leukocytosis is lacking and especially if there is any degree of eosinophilia, allergy should be strongly suspected. A family and past history of allergic diseases is significant and should be inquired into carefully. The diagnosis of abdominal allergy is not easy. The scratch tests, if they work, give us valuable hints as to the presence of an allergic condition and the nature of the etiologic factor. Unfortunately, in abdominal allergy they all too frequently fail us. The intradermal tests are more reliable. They, however, are far from infallible. The tests should be made because, if they do work, they give the diagnosis in a few days and may save many weeks or months of tedious dietary experimentation. If the tests do not work and usually even if they do, we have to carry on systematic dietary study and experimentation to reach a definite diagnosis.

Even if it takes weeks or months to reach a conclusion as to the cause of the symptoms in these chronic sufferers from abdominal allergy, the relief obtained, either by eliminating the offending protein from the diet or desensitizing the patient thereto, is so complete and the unhappy invalid is so easily returned to health without the danger and expense of a useless and unsuccessful abdominal operation that all the time and trouble involved are well spent.

The point I want to stress is that when you are confronted with an acute or chronic abdominal condition in which the symptoms and signs are atypical and the diagnosis is doubtful you should remember that the allergic reactions may occur in any of the abdominal organs and you should give the possibility of your case being one of abdominal allergy serious consideration.

THE RESPONSIBILITY OF THE GENERAL PRACTITIONER IN CHRONIC GLAUCOMA

BENJAMIN ESTERMAN, M D , New York City

BLINDNESS from glaucoma is usually due to negligence on the part of the patient in obtaining medical advice and treatment before the disease is far advanced. The importance of bringing seemingly minor eye complaints to the attention of the doctor is being emphasized more and more by medical organizations, through literature and broadcasts, as well as by the National Society for the Prevention of Blindness. But judging from the large number of self-neglected cases of glaucoma seen in the average eye hospital, the work in this direction, although splendid, needs to be intensified.

Let us assume now that the patient has been convinced and consults his family doctor. Is the average general practitioner able to recognize chronic glaucoma where there has never been a typical acute attack? To be sure, the patient with a red, painful eye or with vision markedly diminished will be sent to the ophthalmologist. But what about the patient whose symptoms may be merely headache, or perhaps nausea, where the visual disturbance seems to him to be relatively unimportant, slight, or to come at a time of day or evening when he does not notice it or expects vision to be dim? Can we be sure that the patient being treated for chronic sinusitis or for some of the disturbances of the climacteric is not also (or instead) suffering from glaucoma? Or that mild attacks often diagnosed as migraine are not in reality transient increases in intraocular tension? Or that headaches and visual disturbances in patients with hypertension, and attributed to that disease, are not manifestations of glaucoma? Or that the man or woman who visits the optometrist because of poor vision is not being contented with a pair of glasses instead of being sent to receive early treatment or surgery for glaucoma? Such cases are fortunately less common than formerly, but they continue to appear frequently in any eye clinic or in the office of any ophthalmologist.

Forgetting for the moment the question of whether optometrists should or should not examine for glasses, the fact remains that many persons go to them for ocular complaints and because they do the optometrists should also take note of the facts mentioned

The refinements of glaucoma detection such as measurement of intraocular tension, plotting blind spots or scotomas, and using the various therapeutic tests, need not be discussed here because they belong in the field of the ophthalmologist. Nor does the average practitioner have facilities for measuring refractive errors or defects in accommodation. The presence of cupping of the optic disks or pulsation of the retinal arteries, if present, are useful signs. Unfortunately, in some cases these signs are not marked. Atrophy and cupping must be distinguished from a wide physiologic excavation, and arterial pulsation must be distinguished from venous pulsation, which is normal. For the practitioner who is not so much at home with his ophthalmoscope as with, let us say, his stethoscope, the difficulties are further increased by the danger of dilating the pupils in suspected cases of glaucoma. But there are certain things he can do to enable him to suspect the presence of glaucoma in its early stages, thus obviating the necessity of referring cases indiscriminately to the ophthalmologist.

The most important facts to keep in mind are that a patient with chronic glaucoma, even moderately advanced (1) may not have noticed diminished acuity of *central* vision, (2) may never have noticed, unless he is extremely alert, a diminution of the *peripheral* visual field until the defect is so marked as to cause stumbling over articles of furniture, etc., (3) may not have experienced ocular pain or, having felt it, either disregarded it or was conscious mostly of supraorbital pain or headache (and considered it sinusitis or "eyestrain"), and above all (4) may *never* have experienced an acute attack (severe ocular pain, headache, red eye, diminished vision, nausea, vomiting, etc.).

This seems to leave us very little but actually shows the need of somewhat more careful questioning. Many early cases will have nothing more than transient periods of dull ocular or supraorbital pain, spells of foggy or cloudy vision, or very commonly a combination of both slight pain and fogging. This is especially apt to occur toward evening or during periods of stress, fatigue, emotion, etc. If these occur at night, the patient may

have observed multicolored halos around distant lights, such as street lamps. *Any case of ocular, supraorbital or frontal discomfort on one or both sides, associated with foggy or blurred vision, is presumptive evidence of glaucoma* and calls for more extensive investigation. This holds true even if the visual acuity on the Snellen Chart is 20/20 at the time of the examination, for many cases of even advanced glaucoma will retain good central vision. And this is also true if at the time of the examination the patient's eyes are entirely uninfamed and do not feel hard to palpation with the finger tips.

The other important sign, which, with a little practice, can be of value to the general practitioner, is narrowing of the visual field. To be sure, quantitative measurement of the field by means of the perimeter or tangent screen is within the sphere of the ophthalmologist. But it is possible for the practitioner to determine a *qualitative* field defect by the following simple method, which can be employed without use of any special apparatus.

The physician and patient stand confronting each other and about 3 feet apart, the patient having his back to the window or other source of light. If the test is performed in the evening, any lights overhead or in front of the patient should be extinguished, leaving only whatever light comes from behind him. The patient is instructed to hold his left eyelid down with the forefinger of his left hand (keeping the other four fingers flexed so as not to obstruct the vision) and to look steadily with his right eye at the left eye of the physician facing him. The physician keeps his right eye closed and, with his left eye, fixes the gaze of the patient's open eye (the patient's right eye and the doctor's left eye are, of course, opposite each other as doctor and patient confront each other).

The patient is shown the test object which need be no more elaborate than a small florist's pin with a white head, preferably about 3 mm ($\frac{1}{8}$ inch) in diameter attached to a thin black or dark gray rod about 12 inches long. He is instructed to say, "Yes" or "I see it," each time this white object is perceived by him at the edge of his visual field.

The physician then holds the object far to the side, as nearly as possible on a plane midway between him and the patient, and brings it slowly toward their line of vision. *If the patient's field is normal, he should perceive the object at the same point as the physician.* If

the field is contracted in that meridian, he will perceive it somewhat further inward. This is repeated for all eight meridians—i.e., nasally, above and nasally, above, temporally and above, temporally, etc. Then the left eye is tested in the same manner—left eye looking at the physician's right eye.

This method actually amounts to the comparison by the examiner of the patient's visual field with his own and, though approximate and qualitative, with practice can be made useful in discovering gross field defect, which in many cases of even moderately advanced glaucoma is the only definite symptom detectable without the use of special methods. Another advantage is that it is rapid, an approximate estimate of the extent of the field in both eyes requiring less than five minutes. It should be stressed that this procedure requires some practice and that this is best done first on a number of cases with normal fields.

Where there is evidence of defect, especially in the nasal portion of either field, in a patient complaining of headache, supraorbital discomfort, or visual disturbance, this also is presumptive evidence of glaucoma.

Summary

1 Diagnoses most frequently made in cases in which chronic glaucoma has been missed or obscured are (a) chronic sinusitis, (b) refractive errors and eyestrain, (c) menopause or menstrual headache, (d) migraine, and (e) vascular hypertension. (Others are retrobulbar neuritis, chronic nephritis, early uremia, brain tumor, iritis, syphilitic meningitis, and multiple sclerosis.)

2 Chronic glaucoma often insidiously goes on to blindness without any of the violent symptoms (inflammation, severe pain, vomiting, etc.) commonly associated with acute glaucoma.

3 A patient with moderately advanced chronic glaucoma may have normal central visual acuity and may not notice loss of peripheral visual field until one eye becomes blind or nearly so.

4 Careful questioning of many patients complaining of headache will elicit associated symptoms, albeit transient, of visual disturbance, fogging, or supraorbital discomfort in glaucoma.

5 A simple method is described by which the general practitioner can determine rapidly, and without special apparatus, whether there is any gross defect in the visual field.

6 Association of headache or visual disturbance or ocular discomfort with defect in the visual field is presumptive evidence of chronic glaucoma

Conclusion

As in many other serious ailments, the difference between a satisfactory outcome and tragedy in chronic glaucoma depends on

early recognition and treatment. To this end it is urged that (1) the education of the patient be furthered so that he will go to his doctor with symptoms that he might ordinarily ignore and (2) the practitioner become more glaucoma-minded in order that he may be able to suspect the presence of the disease in its early phase

983 Park Avenue

MEANINGLESS DICTION IN MEDICINE

Dr Ramsay Spillman, of New York City, recently wrote an interesting letter to the *J A M A* which has aroused approving comment in medical circles. His letter runs

"To the Editor—Twice today I have had telephone calls, from independent sources, stating that a 'complete g-i examination' was desired. On cross examination—which should not be necessary but which I can testify is—it was revealed that an examination of only the stomach was desired.

"How much wasted effort and often expense would be saved if physicians could get together on terminology! To a roentgenologist g means gastro and i means intestinal, and any referring physician who gets on a high horse to my secretary when she tries to find out whether a 'complete g-i examination' means a stomach and colon, a stomach and small intestine and colon, or only a stomach is in a vulnerable position, as people always are who ride on high horses. If the terminology used by many physicians of my acquaintance reflects their school-day teaching, the teaching has been sloppy.

"Another thing that annoys me is for physicians to request a 'g-u examination.' G stands for genital and u for urinary, at least to me, and there is seldom any occasion to examine a man's genital apparatus when the point at issue is a stone in his urinary apparatus. In fact, I have gone to considerable pains to try to educate some of the profession that any irradiation of the germ plasma of any person who is not past the reproductive period—and who can say, in the case of a male, when a patient is past any possibility of reproducing his kind?—is fraught with dire consequences to future generations unless the human germ plasma reacts differently from the germ plasma of the twenty-nine genera of other animals that have been studied to date.

"Another daily request that reflects a total lack of comprehension of semantics is to ask for a 'flat plate.' A plate is made of glass, and I never saw one yet devoted to roentgenographic purposes that was not flat. Glass plates went out not long after hustles did, today films are used, and they are just as flat as glass plates ever were, unless one wants to lay emphasis on the curved cassette that had a vogue a few years ago, even the product of this gadget

was flat when it was put up for inspection. To ask for a flat plate when a film is meant, or even to ask for a flat film, is like asking for an egg omelet. I think that what is meant is a single film as opposed to a stereoscopic pair, at least the context practically always leads to that conclusion. It doesn't mean that it is desired to have the patient flat on the table, because I am frequently asked for a 'flat plate upright' when the question is the determination of the presence of air under the right diaphragm in a case of suspected perforated ulcer.

"As I get older, I look back with even more sympathy than I had at the time on my erstwhile professor of surgery Charles L. Gibson, who invariably interrupted the student who mentioned 'lymph glands' with 'please don't say lymph glands in my clinic,' and would explain that glands are epithelial structures with a secretion, which lymph nodes quite definitely are not. One can search the whole world over but will never find a Cornell graduate of Gibson's time who will say 'lymph glands.' However, the misuse of the term is so well nigh universal that if a man says 'lymph nodes' one can bet with reasonable safety that he was once a student of Gibson's.

"To go out of my own field, which I was never averse to do, I should like to pay my respects to the persons who can spare no longer designation for the wares of the string galvanometer than 'E.K.G.' To ask for an elektrokardiogramm by the initials of its component German words is to pay homage to a language which at the moment is not identified with scientific freedom. If Einthoven could go to the trouble to invent the string galvanometer, I think people should go to the trouble to pronounce 'electrocardiogram.' I'm not saying that I think they will, I'm just saying that I think they should.

"The late Dr E. W. Caldwell used to say that roentgenology would be an enjoyable occupation if it weren't for the patients. I will modify that to say that roentgenology wouldn't be so had if physicians would only tell the roentgenologist what they mean. There used to be a song upward of thirty years ago—if I recall correctly, it was in a show of Raymond Hitchcock's—that went, 'If people said the things they mean, And meant the things they say' It's still good."

CHEERIO!

"An optimist laughs to forget, a pessimist forgets to laugh."
—*Ills Med J*

WHY NOT DO IT THEN?

"If all men who sleep in church were laid end to end, they would be more comfortable."

OCCUPATIONAL ASTHMA AND VASOMOTOR RHINITIS

An Outline of Some Common Industries Where These Symptoms Are Initiated

LOUIS STERNBERG, M D , and ALAN H. SORRELL, M D , New York City

THAT allergies of the respiratory tract can be induced by occupational contact has been known for years. Here the worker inhales chemicals, drugs, and the various dusts that emanate from the different materials in his daily routine. Modern industrial pursuits have added to the incidence of asthma and vasomotor rhinitis in subjects that are hypersensitive.

We shall discuss only those cases where the occupation is of primary importance to the one who is potentially allergic. This means that we shall not deal with those occupations that act as aggravating factors through physical or chemical means—such as irritating fumes, odors, etc. We shall endeavor to outline those common industries where the potentially sensitive individual comes in direct contact with certain antigens (allergens) to which he becomes specifically sensitized through direct exposure after a variable period of time.

The principal symptoms produced in these allergies of the respiratory tract are those of asthma, vasomotor rhinitis, or both. Symptoms of vasomotor rhinitis may precede or follow an attack of asthma, or these nasal symptoms may be present in various degrees without any asthmatic manifestation. Asthma, however, is usually more frequently observed. The prodromal symptoms may first appear with a mild cough or slight dyspnea during working hours. Later they may become so severe that the patient may find it impossible to continue his particular duties.

The occupations that can initiate the above symptoms are quite numerous and depend upon the industry of a particular region or location. Although these occupations do not present a hazard to the majority of workers, they ultimately do become such to a small number of individuals who have an allergic background or tendency.

Positive skin reactions are usually obtained in these industrial allergies when the causative agent is not a chemical or drug. (However, drugs that are of a protein nature, such as caroid, lycopodium, etc., may give skin reactions.) Chemicals and drugs are poor antigenic substances. Hence, those patients whose symptoms are induced by these ma-

terials rarely have floating antibodies (reagents) in their blood stream. Chemicals and drugs, therefore, may cause asthma or vasomotor rhinitis in a hypersensitive individual without one being able to elicit a positive skin reaction with them. Occasionally, we do see a positive skin reaction with a chemical or drug, but that is rather rare, and when it does occur it may become extremely dangerous in creating a constitutional reaction. Intradermal tests with these materials, therefore, should always be attempted with the greatest caution and with highly diluted extracts at first. If no reaction takes place, higher concentrations can be tried later on. The novice in this field will be safer in trying the scratch or scratch-patch test instead. Hence, before a diagnosis is made in a patient where a drug or chemical is suspected we may have to depend upon a careful history, on the physical examination, and on a microscopic search of the nasal and bronchial secretions and of blood for an increased eosinophil count. Frequently, we have to resort to an environmental test—of great assistance in these particular cases.

The ideal treatment of these respiratory allergies should be based upon the removal of contact of the offending cause. As this is usually not practical to most workers, hypsensitization should be tried so as to increase the tolerance of the particular antigen. When one deals with a chemical or drug this should not be attempted for reasons already mentioned.

The following workers are most commonly affected in this region: bakers, furriers, metal polishers, coffee, soy, cacao, and castor bean handlers, refrigerator workers, jewelers, hat makers, rag sorters, woodworkers, poultry dealers, pharmacists, upholsterers, and beauticians.

Bakers—Bakers come in contact with flour, and those who are allergic may develop a sensitivity to wheat, rye, buckwheat, etc. Hallermann¹ states that intracutaneous tests are unreliable and suggests that these be made by blowing the flour on the nasal mucosa. Uhrbach and Wiethel², as well as Hallermann,¹ have had good results by injecting the antigen into the nasal mucosa. We never had to resort to this form of diagnosis, for in the great

majority of cases we did get positive skin reactions by means of the intracutaneous method, using an extract of the suspected flour. Treatment is fairly satisfactory by means of hyposensitization with the offending antigen. Wearing a mask or a filter is of great benefit, but unfortunately few of these workers wear such protectors because of the fear of losing their position when discovered that they are sick.

Furriers—Furriers may become sensitive to (a) the fur itself, (b) "paraphenylenediamine" (ursol D), which is the most common dye used, or to any of the seventy-eight different ursols, (c) some insecticide, such as "paradychlorbenzine" that is generally used in the fur trade²³, or (d) "chumondumin," an incomplete oxidation product resulting from the reaction of hydrogen peroxide and ursol. In the final stages of the dyeing process the fur is washed with hydrogen peroxide in order to remove any of the unused dye. A careful history is of great importance. The worker is often able to state the particular fur, chemical, or dye that brings on the asthmatic attack.

It is important to remember that most of the cheaper grade furs are usually dyed, or otherwise prepared, rabbit fur. Rabbit skins that are not of a pure white color are dyed, sheared and plucked, and made to resemble almost any genuine fur. They are prepared as cheap substitutes for sable, hudson seal, red fox, lynx, mink, mole, nutria, etc.³ White rabbit skins undyed are sold as white fox or, when bleached, as ermine. It is, therefore, not unusual to find a patient who states that he gets an asthmatic attack when in contact with ermine or white fox but gives a negative skin reaction to these particular furs and a positive reaction to rabbit hair.

In the process of dyeing, furs lose most of their antigenic material. Therefore, they rarely initiate allergic symptoms from their original dander, which has been washed off or altered completely. However, when a dyed fur is suspected we have to think of the other possible factors that might have entered, such as a ursol preparation, chumondumin, or some insecticide.

That the dyes may cause a varied amount of asthma or vasomotor rhinitis among furriers has been known for many years. Criegern,⁴ in 1920, published 40 cases of "poisoning caused by chumondumin." Curschmann,⁵ in 1921, presented 6 cases of ursol asthma. He stated that the allergen was not ursol but its oxidation product, chumondumin. He further stated, as also did Mehl⁶ and Gerdon,⁷

that the symptomatology was due to a hypersensitivity. Genkin and Owtschinski,⁸ after a study of 31 cases of ursol asthma, all of which gave negative scratch tests, thought as did Bock⁹ and Meyer¹⁰ that allergy was not the cause and again revived the toxic theory of ursol asthma. Forker,¹¹ in 1935, in his work on the various types of ursols states that seventy-eight different ursols are used in the dyeing industry. Of all these, the chemical formulas of twelve are known. The rest could not be determined because, as the dye manufacturers stated, "a trade secret was involved." The ursols are usually denoted by a letter or group of letters, i.e., ursol D, DD, 2GA, etc. Forker¹¹ tested patients with ursol asthma with a 2 per cent ointment (patch tests) using thirteen different ursols and found that only six gave strongly positive reactions. He concludes that tests on a patient with ursol asthma should be made not only with ursol D but also with ursols DD (gray-white), DF (black-gray), SB (black-blue-gray), DMG (black), P (dark gray-black), and NZ (light gray-blue).

Hyposensitization of these cases is practically impossible, and an effort must be made to avoid the causative agent. This may sometimes be accomplished by shifting the worker to a different part of the plant.

Beauticians—The most common cause of symptoms in beauticians are the powders and rouges that contain orris root. The process of dyeing hair (ursol or henna) may cause respiratory symptoms.

Another cause of asthma or vasomotor rhinitis in these workers appears to be the hair-setting fluid used in hair waving. Feinberg¹² states that the usual composition of hair-setting materials (as given in a U. S. Department of Agriculture *Bulletin*) are quite varied and, among other things, contains acacia, gum tragacanth, linseed gum, quince-seed gum, karaya gum, various flaxes, and inorganic compounds. Bullen¹³ reported a patient with allergic rhinitis, and by applying Cooke's postulates definitely showed the case to be caused by karaya gum. In a discussion of the paper Baldwin referred to quince-seed gum in a hair lotion and also stressed the atopic sensitivity to acacia. Grant,¹⁴ in 1932, reported a positive skin test to flaxseed in a patient who was using a hair-wave preparation. One of us (L. S.) is treating a hay-fever patient (beautician) who used to develop attacks of asthma whenever she gave a permanent wave to a customer. She gave marked skin reactions to the hair-wave lotion that she was using and

also to indian gum These tests were also positive on passive transfer It is only after a careful history is elicited and the causative agent is found that the worker can be told what to avoid in order that the recurrent attacks be controlled

Hat Makers—Hat makers come in contact with many materials used in the making of felt—such as rabbit hair, cotton, wool, and silk Sometimes they are found sensitive to a bleaching agent used in the manufacture of these hats Banana oil and oxalic acid are the most common used in this trade We were able to get a positive scratch test with the banana oil in 1 out of 2 patients This patient was advised to look for some other employment since treatment with the oil could not be tried for fear of a constitutional reaction

Jewelers—In reference to jewelers, one of us (L S) recently observed a patient whose attacks of asthma occurred only on days when rings were being made from molten ore Here the gold is poured into molds made of cuttlefish bone, and fumes are given off when the ore contacts the mold This patient gave a marked skin reaction to the cuttlefish bone extract His passive transfer test was also positive Another patient, also a jeweler by occupation, developed attacks of asthma whenever he used cuttlefish bone for polishing purposes He likewise gave marked skin reactions to cuttlefish extract His Prausnitz-Küstner test was also positive It is interesting to note that in both of these cases all other skin tests were negative, including all other fish extracts used The second patient received a fair result from hyposensitization with cuttlefish extract The first was able to eliminate contact Weston¹⁵ reported a similar case in 1930 Markin¹⁶ demonstrated a case in a jeweler who was sensitive to the dust (boxwood) shavings used in polishing gold This patient improved when placed in a smaller shop where this procedure was not carried out

Rag Sorters—Rag sorters may be sensitive to the particular type of rags they handle (wool, cotton, silk, linen, etc), or they may become sensitive to the dust present in their factory In a recent case that we came across the patient had been a rag sorter for three years He complained of asthma of four months' duration Skin tests with inhalants, contactants, and stock dust were negative An extract prepared from the dust of the factory where he was employed gave a positive skin reaction Hyposensitization did not help him very much, and he was obliged to give up his occupation

Leaky refrigerators give off sulfur dioxide, and those sensitive to this gas often get attacks of asthma and vasomotor rhinitis Dowling,¹⁷ in 1937, reported a case of asthma following prolonged exposure to sulfur dioxide Romanoff¹⁸ has recently published 3 such cases There is no method of skin testing for sulfur dioxide which we possess at the present time The case that came to the attention of one of us (L S) was a counterman in a restaurant who developed asthma whenever the refrigerator became out of order He developed symptoms hours before anyone was able to notice the offending gas These included itching of the eyes, sneezing, and coughing When the gas became more concentrated he began to wheeze During two of these attacks adrenalin chloride was required to give him relief This patient was also a hay-fever sufferer, sensitive to ragweed, but never suffered from asthma except when his refrigerator was out of order

Metal Polishers—Metal polishers use different kinds of rouge in their occupation This is a mixture of various resins, bichromates, oxalic acid, and turpentine Those sensitive to these chemicals usually give negative skin reactions but do give a definite history of asthma while at work Treatment, whenever possible, is elimination or change of occupation

The *coffee bean* may cause allergic manifestations not only when ingested but also when inhaled Walzer¹⁹ mentioned several cases of respiratory allergy among grocers who ground their own coffee Walker²⁰ and Rich²¹ also mention several cases of asthma and vasomotor rhinitis in coffee sifters One of us (L S) has come across a patient who worked in a coffee plant and suffered attacks of asthma whenever he entered the roasting chamber Another patient suffered from both asthma and vasomotor rhinitis whenever she inhaled the fumes from the coffee that she prepared while working in a restaurant Both cases gave positive skin reactions to coffee extract They were also positive on passive transfer The second case improved with hyposensitization Another patient had marked vasomotor rhinitis for five years when in contact with cacao beans in a cacao bean warehouse He developed these symptoms after fourteen years of exposure and was quite comfortable week ends at home He gave positive skin reactions to a cacao bean dust collected in the warehouse and also to chocolate He has improved under treatment with the dust mentioned

Poultry Dealers—Poultry dealers sometime

majority of cases we did get positive skin reactions by means of the intracutaneous method, using an extract of the suspected flour. Treatment is fairly satisfactory by means of hyposensitization with the offending antigen. Wearing a mask or a filter is of great benefit, but unfortunately few of these workers wear such protectors because of the fear of losing their position when discovered that they are sick.

Furriers—Furriers may become sensitive to (a) the fur itself, (b) "paraphenylenediamine" (ursol D), which is the most common dye used, or to any of the seventy-eight different ursols, (c) some insecticide, such as "paradychlorbenzine" that is generally used in the fur trade²³, or (d) "chimondimin," an incomplete oxidation product resulting from the reaction of hydrogen peroxide and ursol. In the final stages of the dyeing process the fur is washed with hydrogen peroxide in order to remove any of the unused dye. A careful history is of great importance. The worker is often able to state the particular fur, chemical, or dye that brings on the asthmatic attack.

It is important to remember that most of the cheaper grade furs are usually dyed, or otherwise prepared, rabbit fur. Rabbit skins that are not of a pure white color are dyed, sheared and plucked, and made to resemble almost any genuine fur. They are prepared as cheap substitutes for sable, hudson seal, red fox, lynx, mink, mole, nutria, etc.³ White rabbit skins undyed are sold as white fox or, when bleached, as ermine. It is, therefore, not unusual to find a patient who states that he gets an asthmatic attack when in contact with ermine or white fox but gives a negative skin reaction to these particular furs and a positive reaction to rabbit hair.

In the process of dyeing, furs lose most of their antigenic material. Therefore, they rarely initiate allergic symptoms from their original dander, which has been washed off or altered completely. However, when a dyed fur is suspected we have to think of the other possible factors that might have entered, such as a ursol preparation, chimondimin, or some insecticide.

That the dyes may cause a varied amount of asthma or vasomotor rhinitis among furriers has been known for many years. Criegern,⁴ in 1920, published 40 cases of "poisoning caused by chimondimin." Curschmann,⁵ in 1921, presented 6 cases of ursol asthma. He stated that the allergen was not ursol but its oxidation product, chimondimin. He further stated, as also did Mehl⁶ and Gerdon,⁷

that the symptomatology was due to a hypersensitivity. Genkin and Owtschunski,⁸ after a study of 31 cases of ursol asthma, all of which gave negative scratch tests, thought as did Bock⁹ and Meyer¹⁰ that allergy was not the cause and again revived the toxic theory of ursol asthma. Forker,¹¹ in 1935, in his work on the various types of ursols states that seventy-eight different ursols are used in the dyeing industry. Of all these, the chemical formulas of twelve are known. The rest could not be determined because, as the dye manufacturers stated, "a trade secret was involved." The ursols are usually denoted by a letter or group of letters, i. e., ursol D, DD, 2GA, etc. Forker¹¹ tested patients with ursol asthma with a 2 per cent ointment (patch tests) using thirteen different ursols and found that only six gave strongly positive reactions. He concludes that tests on a patient with ursol asthma should be made not only with ursol D but also with ursols DD (gray-white), DF (black-gray), SB (black-blue-gray), DMG (black), P (dark gray-black), and NZ (light gray-blue).

Hyposensitization of these cases is practically impossible, and an effort must be made to avoid the causative agent. This may sometimes be accomplished by shifting the worker to a different part of the plant.

Beauticians—The most common cause of symptoms in beauticians are the powders and rouges that contain orris root. The process of dyeing hair (ursol or henna) may cause respiratory symptoms.

Another cause of asthma or vasomotor rhinitis in these workers appears to be the hair-setting fluid used in hair waving. In a discussion of the paper Baldwin referred to quince-seed gum in a hair lotion and also stressed the atopic sensitivity to acacia. Grant,¹⁴ in 1932, reported a positive skin test to flaxseed in a patient who was using a hair-wave preparation. One of us (L. S.) is treating a hay-fever patient (beautician) who used to develop attacks of asthma whenever she gave a permanent wave to a customer. She gave marked skin reactions to the hair-wave lotion that she was using and

THE USE OF VITAMIN K IN OBSTRUCTIVE JAUNDICE

GEORGE S REED, M D , Syracuse, New York

THE problem of the jaundiced patient is not new. The types of jaundice and their causes are well known. Fortunately, the type classified as obstructive jaundice is the least frequent of the entire group, and it is in this class that hemorrhage, the thing that has given us so much anxiety, occurs. I shall limit my presentation to cases of obstructive jaundice caused by common bile duct obstruction, either from stone, tumor, injury, or pathology in the head of the pancreas and, likewise, that due to obstruction in the liver from some pathology not clear.

For years the chief concern in the treatment of obstructive jaundice has been what to do about the hemorrhage if and when it occurs. We have all tried the following methods to prevent or relieve such a condition: transfusions of whole or citrated blood, calcium in many forms, serums and chemicals to improve blood coagulation, and all these things often to no avail. Now at last it appears that a method has been discovered by which hemorrhage can either be prevented or stopped when it does occur.

In 1935, Dam, a Scandinavian scientist, showed that the lack of a fat-soluble substance, which he called vitamin K (coagulation vitamin), in the diet of chicks led to fatal bleeding. He opened a new approach to the study of pathologic bleeding. Investigation of a hemorrhagic disease in cattle caused by eating spoiled sweet clover had led to the demonstration of a low plasma prothrombin as an etiologic factor, presumably due to toxic effect upon the liver. Improvements in methods of determining plasma prothrombin were followed by observation of low plasma prothrombin in animals with experimental liver poisoning and biliary obstruction, in chicks with hemorrhagic diseases and vitamin K deficiency, and in patients with obstructive jaundice.

Another link was supplied in the chain by the experimental proof that fat-soluble vitamins were not absorbed from the intestine in the absence of bile salts. Practical application of these facts has led to successful treatment of prothrombin deficiency in patients with liver disease by means of extracts containing vitamin K. Much study has been

given to developing methods of assaying the vitamin K content of various animal and vegetable fats, but the method based on the protective or curative effect on chicks must still be used.

So much for a small part of the history of the development of the use of this principle from 1935 to January, 1938, when the first patient was treated for obstructive jaundice with hemorrhage. It was during this latter year that several clinics took up the work, and one clinic reported late in that year 26 cases treated with this method. Of the 26 reported, only 3 of the cases had hemorrhage following operation. Many of the reports of experiments with vitamin K on animals and humans covered in this paper are dated as late as January, 1939. Thus, you see the practical application of the work of Dam and several collaborators in this country has only recently been applied.

With these facts in mind, the following is a presentation of 3 cases of obstructive jaundice.

Case Reports

Case 1—A woman, aged 47, in 1935 had her first digestive symptoms, consisting of upper abdominal pain and indigestion, that gradually grew worse. This course lasted for two years. She consulted a physician in another city in 1937, and in that year a cholecystectomy was done. After the operation she had one episode of acute pleurisy in the right side of the chest. Other than that she made a good recovery and was in good health for several months. However, two years later she developed intermittent jaundice, again had pain in the epigastrium and, finally, bleeding from the vagina. She came to the University Hospital on March 22, 1939. At this time the patient appeared quite frail, suffering from chills, fever, epigastric pain, and pain in the back. She had lost 10 pounds. Her hemoglobin was down to 42 per cent, red cell count, 1,850,000, polymorphonuclears 63, lymphocytes, 28 per cent, eosinophils, 10 per cent, basophils, 1 per cent, and icteric index, 75.

Studies were done and observations made, and it was felt that this woman had a common duct obstruction, although the chills and fever and some enlargement of the liver made one suspicious of a cholangitis.

A nine-day preoperative preparation was carried on during which two transfusions, liver extracts, furrow sulfate by mouth, and high carbohydrate diet were given. Blood studies the

suffer from an occupational allergy. Feathers is a common causative agent (also among upholsterers). Recently, one of us (L. S.) came across a case of asthma in a butcher who suffered from asthmatic attacks every Thursday and Friday. Coincidentally, these were the days on which he handled chickens that were brought in for sale over the weekend. He gave marked skin reaction to feathers and was improved by treatment. Brown²² discusses 3 cases of asthma caused by chicken feed (active ingredient linseed meal) in poultry dealers. Nicholson,²³ testing 158 patients, found 44 per cent sensitive to flax and linen.

Pharmacists and Chemists—Attacks of asthma and vasomotor rhinitis may be had by pharmacists and chemists when in contact with certain drugs or chemicals that they inhale in their occupations. Of these the most common, according to Peshkin,²⁴ are ipecac, caroid, rhubarb, and lycopodium. In laboratory workers, urease, peptone, podophyllin, vanilla and castor-bean dust (Figley and Elrod²⁵) are known to bring on symptoms in the hypersensitive individual.

Woodworkers—Woodworkers frequently become hypersensitive to the particular type of wood with which they come in contact. Gade²⁶ found that 74 out of 100 woodworkers died with complications of the upper part of the respiratory tract. He examined 20 woodworkers and found 14 had symptoms of upper respiratory nature. Of these 14, 7 had asthma. Unfortunately, no skin tests were done. Bahn²⁷ states that intracutaneous tests in these patients are usually positive with an extract of the particular wood that causes their symptoms. They believe that "desensitization" does not give satisfactory results.

Upholsterers—Upholsterers work with a great variety of allergenic materials. It is, therefore, not surprising that these people have a relatively high incidence of allergic manifestations. In furniture-stuffing the common materials used are feathers, cotton, animal hair (horse, rabbit, and goat), wood shavings, vegetable fiber (kapok, cotton, etc.). Careful history-taking is of great importance in these cases so that some attempt be made to discover the causes of the patient's trouble before skin tests are performed. Since most of the allergens used in the upholstery industry are so common and varied, it is practically

impossible to remove oneself from their contact. Hyposensitization should, therefore, always be attempted in these cases.

Conclusions

- 1 A list of industries is given which are capable of inducing asthma and vasomotor rhinitis in certain predisposed individuals.
- 2 The diagnosis in most of these cases is not difficult but extremely important.
- 3 Many of these patients can be tested by the intradermal method.
- 4 Intradermal tests should be performed with the utmost caution when testing an allergic individual with a chemical or drug.
- 5 The ideal treatment in most of the industrial allergies is in the removal of the offending cause.

SLIGHT HANDICAP

"I wish the boys wouldn't call me Big Bill"
"Why?"

"These college names stick
ing to be a doctor"
And I'm studying—
—Kablegram

bladder was large but essentially negative. A cholecystogastrostomy was done. Although this man had no hemorrhage before or after operation he was given 1 vitamin K capsule and ox bile, 10 grains, three times a day, until discharged from the hospital on December 13, 1939.

Is it not fortunate that science has evolved so many procedures to safeguard the lives of patients, both in medicine and surgery? Bleeding and clotting time were done in all the cases reported above. However, these tests are not a proper safeguard. They are not accurate and do not give the true picture. In obstructive jaundice the prothrombin test should be done on all cases for surgical control and safety. The quick test, so-called, is now being quite universally developed and is the one mentioned in the third case quoted in this paper. The majority of obstructive jaundice patients have a prolonged prothrombin time, and this is particularly so where liver damage is found, since bile is not getting into the intestinal tract and is much like a bile fistula.

At the present time there are two kinds of preparations on the market. One is vitamin K capsules (in oil), containing 1,000 units, and the dose is 1, 2, or 3 capsules daily until the prothrombin test has been materially reduced. The ox bile is the ordinary commercial ox bile, which is soluble in normal saline and can be obtained as such. At the present time the only intraduodenal preparation is called "Klotogen." It is liquid and is given in 2- to 8-cc doses or 10,000 units at a time intraduodenally. In a short time, the pharmacist informs me, there will be a new synthetic preparation of vitamin K on the market which will be much easier to handle.*

* Vitamin K for medical and surgical use is now easily obtained. This is (a Council-designated trade name) Menadiolone (2-methyl-1,4 naphthoquinone) in ampules 0.3 and 1 cc containing 10 and 32 mg vitamin K respectively.

Clinically, for treatment purposes, obstructive jaundice may be divided into two classes, i.e., those without hemorrhage, which may be treated by mouth with vitamin K and bile, and those with prolonged prothrombin tests or with hemorrhage, which should only be treated by the intraduodenal method. In all cases where the blood count is down, transfusions must be given. Mouth dosage and intraduodenal methods are the most reliable. Vitamin K in oil given by hypodermic is not as reliable and takes too long to be absorbed. It is likewise said not to be as pure as it should be for this purpose. Another interesting point regarding transfusions has come out in this procedure—transfusion should be made with fresh blood from a donor. Blood from a blood bank, because of its decreased prothrombin content, is not advisable.

Conclusion

As vitamin K is inexpensive, it is probable that it will be used routinely in patients with obstructive jaundice, both before and after surgery, even though no prothrombin deficiency is found. By this means the frequency with which indications for transfusions arise may be reduced.

THE WIFE OF THE MAN WHO WAS NOT THERE

Oh, for the life
Of a doctor's wife!
It's a wonderful life, it's fine!
You struggle to fix
His dinner by six,
And he doesn't get home till nine.

You play the host,
You carve the roast
And pray he'll return from his call
He's invariably late
To a play or a date—
Or he doesn't turn up at all.

Oh, for the life
Of a doctor's wife!
It's a wonderful life, I've found
Your finger gets cut,
And it's falling off, but
You can't find a doctor around.

So pity the spouse
Of the doctor's house!
The spouse of the house sublime,
For, though she is wed,
It may truly be said
She is husbandless most of the time
—Juliet B. Furman, M.D., in JAMA

day before operation showed the hemoglobin to be 77 per cent, the red cell count, 3,760,000, the bleeding time, three minutes, and the clotting time, four and one-half minutes. Knowing something about vitamin K, we finally succeeded in obtaining some for postoperative treatment, especially for intraduodenal use.

On April 1, 1939, an exploration of the common bile duct was found without obstruction, the pancreas was normal, but the liver was badly damaged. A T tube was inserted in the common bile duct and the abdomen was closed. This patient progressed normally with her postoperative course until the fifth day, when vaginal bleeding started again and the wound dressing became saturated with blood. The patient complained of tasting blood in her mouth, and there was a thin trickle of blood from the common bile duct drain. Immediately we prepared to use vitamin K and bile. A preparation called Klotogen, 8 cc with 2 Gm of bile salts dissolved in 200 cc of saline, was injected intraduodenally. This was immediately followed by a transfusion of 500 cc of citrated blood. Each day thereafter, the same amount of Klotogen (vitamin K) and bile was instilled into the duodenum until the fourteenth postoperative day. Transfusions were repeated on the tenth and twelfth days, and on the tenth day the patient felt much improved, sitting up in bed and taking a fairly abundant diet. On the fourteenth day the last bleeding was seen on the dressings, from the drainage tube, and from the vagina. An increased amount of bile was obtained from the tube, and the common bile duct was injected with lipiodol, x-rayed, and found to be unobstructed. On the twenty-fifth day the patient got out of bed, was eating well, and had no hemorrhage, and on the thirty-ninth day she was sent home.

Case 2—This case came in two months after the first one, and we approached it with a feeling of much greater confidence. In September, 1938, an obese woman aged 40, weighing 230 pounds, came to the hospital with every symptom of gallbladder disease. She was worked up carefully and a cholecystectomy was done at this time. The gallbladder and common duct were so closely associated that an injury was done to the common bile duct necessitating an anastomosis with the duodenum. She made an uneventful recovery and went home about the third week. She remained well until March of the following year when her skin began to itch and she became a little jaundiced. She returned to the hospital on May 14, 1939, for examination. It was felt that she had a mechanical obstruction of the bile duct and that this would have to be relieved. Her jaundice was deepening, her stool was clay colored. The laboratory examination showed 12 Gm of hemoglobin, 3,900,000 red cells, 7,500 white cells, 63 per cent polymorphonuclears and 30 per cent lymphocytes. Her icteric index was 75, bleeding time,

four minutes, and clotting time, eight minutes.

The period of preoperative preparation lasted four days and consisted of a high carbohydrate diet, 15 Gm ox bile three times a day, and one blood transfusion. An exploratory operation revealed the common duct completely shut off from the duodenum. Obstruction was relieved, and reanastomosis to the duodenum was done. The liver appeared to be normal, and a T tube was put into the common bile duct and into the duodenum. In the afternoon of the first postoperative day, 1 vitamin K capsule and 10 grains of ox bile were given three times a day by mouth and continued daily for twenty-one days. A day or two after the operation we were obtaining from 500 to 850 cc of bile drainage, and it was decided to use a portion of this bile for treatment. For each of the four succeeding days, 350 cc was instilled in the duodenum. Bright red blood was seen on the dressings on the second day after the operation. The dressings were partially saturated each day until the tenth postoperative day when bleeding ceased. One 500 cc of citrate transfusion was given, the common bile duct was x-rayed with the aid of lipiodol and found patent.

The patient was discharged on the twenty-ninth postoperative day with the T tube still in place and draining a fair amount of bile.

Case 3—A man, aged 55, was admitted to the University Hospital on October 16, 1939. His history revealed constipation for six weeks, excessive use of alcohol, and five weeks of jaundice, with badly itching skin, epigastric pain, occasional vomiting, clay-colored stools, and the loss of 41 pounds in weight. There was no definite history of gallbladder pathology. The liver was large and tender. A blood count showed 11 Gm of hemoglobin, 4,400,000 red cells, 11,200 white cells, 77 per cent polymorphonuclears, and 20 per cent lymphocytes. There was no change in the red cells. The urine was essentially negative except for a positive bile test and a few red and white blood cells. The icteric index was 100, bleeding time, two minutes, and clotting time, eight minutes. This man was given a preoperative preparation consisting of 1 vitamin K capsule, with 10 grains of ox bile by mouth three times daily. On November 3, after some treatment with the ox bile and vitamin K, his prothrombin test by the quick method was thirty seconds and his control was 40 (normal 22 to 25). (This by the way is the first time we have seen a prothrombin test of any kind, and this was worked up by one of our interns at University Hospital.) On November 8 his prothrombin test was still thirty-five seconds, the control was 20, and the coagulation time was nine and one-half minutes. Preoperative treatment was continued until November 28, almost twenty-five days, when an exploratory operation was done and a mass was found in the head of the pancreas. The gall-

day From three to ten injections are used, depending upon the need Others have recommended larger doses and shorter intervals between treatments

In 1935 A. L. Brown⁴ advanced the concept that protein injections produce their effect by a nonspecific "interfering" action of the specific antiprotein immune substances He pointed out that both specific and nonspecific antibodies were produced by foreign protein injections

Other foreign proteins have been used, such as diphtheria antitoxin and filtrates of pathogenic organisms Foreign proteins should not be used if the patient's general condition is poor because of fever, heart disease, or low vitality (Noe⁵ and Newton⁶)

Everyone is familiar with the sodium salicylate treatment as recommended by Gifford⁷—up to 1 gram of sodium salicylate per pound of body weight daily Large doses of salicylates by mouth are tolerated when given mixed with effervescent alkaline salts Pilocarpine sweats, combined with mercury rubs and iodides, have also been recommended Iodides alone in the later stages of subacute uveitis are valuable in hastening the absorption of the vitreous opacities

After the acute symptoms of uveitis have subsided, if the etiology is found to be syphilis, tuberculosis, or brucellosis, specific therapy should be started

The diagnosis of uveitis due to tuberculosis is not easy It must be made on the basis of clinical observations, and not on the basis of the tuberculin skin test, which may be negative Adler⁸ states that miliary tubercles with little inflammatory reaction may be seen in the iris by slit-lamp examination and in the choroid if the metastasis occurs shortly after the primary lesion has developed and before allergy is developed This may be found in young people of from 10 to 25 years of age Between 25 to 35 years of age the tubercular iritis is more inflammatory, synechiae form, and sclerosing keratitis may develop In the choroid, large greenish gray lesions, usually single and in the periphery, may be seen. The vitreous humor is hazy and the skin sensitivity is often high

Patients from 30 to 50 show ciliary body involvement as well as iritis, and the process is highly exudative Mutton-fat deposits on the cornea are characteristic The skin reaction is usually positive

The treatment is that for general tuberculosis—fresh air, rest, high caloric diet, etc Brown⁴ believes that this is the most important measure Sodium gold thiosulfate has been

used in Europe and by Benedict⁶ Nonspecific syphilitic treatment has been used especially where the diagnosis is not certain.

The specific treatment is tuberculin, which should be used in the allergic type of case but not in the tuberculosis-infected lesion in which it may produce injury (Eggston¹⁰) The initial dose should be one-tenth of the dose required to give a skin reaction.

The perifocal theory of tuberculin therapy regards allergy as responsible for local immunity and attempts to create local immunity by use of tuberculin Inactivity of the lesion is interpreted as attainment of local immunity, and the therapy is then stopped Blinded, phthisical eyes often result from this therapy

The desensitization concept sponsored by Woods¹¹ is based on the fact that allergy and immunity are unrelated Tuberculin is used for long periods, and the dose is steadily increased during periods of remission to maintain the desensitization Patients extremely sensitive to tuberculin must be treated cautiously with small amounts, being careful not to produce a local reaction. It may be necessary to start with 0.000,001 mg or less The tuberculin therapy is discontinued only if the skin tests become almost totally nonreactive and the ocular lesion has remained nonreactive for a year or more Woods says that paracentesis causes an amazing improvement in these cases He also advocates the use of beta radium rays, which penetrate only 2 or 3 mm

Since these rays are obtained from radon, which is not available in Rochester, I have recently been using the superficial radiation from a new small therapeutic x-ray machine* whose rays approximate beta radiation in depth of penetration. A marked reduction in corneal vascularization results I have not yet determined the effect on lesions of the iris and ciliary body

Undulant fever (Malta fever) or brucellosis may be a cause of chronic uveitis Green¹² called attention to this in his paper before the American Ophthalmological Society in 1938 The disease is more widespread than is generally realized

The blood agglutination test for brucellosis is of value only when positive It is negative in 90 per cent of the chronic cases The skin test with intradermal injection of killed bacillary suspension gives a positive reaction in twenty-four hours, which may last three days or more and is often quite severe An opsonocytophagic test is reported by Dr Green

*Picker portable x-ray machine with a capacity of 15 milliamperes and 50 kilovolts. We have used 40 kilovolts without a screen.

THE TREATMENT OF UVEITIS

JOHN F. GIPNER, M.D., Rochester, New York

THE treatment of uveitis varies with the chronicity of the disease process. Acute uveitis requires active vigorous treatment, first, to prevent posterior iris synechia and second, to reduce the inflammation as quickly as possible in order to prevent serious permanent damage to the ocular tissues. In the chronic forms the immediate danger of lasting injury to the ocular tissues is not present and adequate time is available for a thorough and complete search for the cause.

In acute uveitis, early dilatation of the pupil can be accomplished by the use of drugs that stimulate the iris dilator fibers in conjunction with the use of 2 per cent atropine ointment. Cocaine may be employed or 1 to 1,000 epinephrine chloride solution may be used on a cotton pledget placed under the lids, or 2 to 3 minims may be injected subconjunctively. Two per cent epinephrine bitartrate or levoglucosan may also be used. Dionin is said to promote absorption and increase the activity of atropine. Leeches have been generally abandoned yet they may still be of value in relieving severe, painful iritis.

After the steps to dilate the pupil have been taken, the use of local heat is the next most important local treatment. This may be applied by hot compresses, the altherm, dry heat or medical diathermy.

In a small number of acute anterior uveitis cases there is an increase in the intraocular tension. Occasionally, it can only be differentiated from primary glaucoma by the use of the slit lamp to determine the condition of the aqueous humor. Epinephrine should first be tried and, if it fails to control the pressure, paracentesis of the anterior chamber may be performed. If the pressure stays up for weeks in spite of these measures, an iridectomy should be done. This is usually followed by a severe reaction. Nevertheless, the results are better than those following cyclodialysis, and filtering operations close up with scar tissue.

The cause of acute uveitis should be found within the first two days if possible. The blood for the Wassermann and Kahn tests should be taken before protein therapy is started. The tuberculin and brucellosis skin tests should be done as soon as practi-

cable. If gelatinous iritis is present and the urologist finds genitourinary gonorrhea, artificial fever treatment, properly timed to outlast the thermal death time of the strain of gonococcus found, offers the best results. If this therapy is not available, then foreign protein therapy and prostatic massage is the next best treatment. Gayton¹ found that sulfanilamide, which works especially well in the treatment of acute gonorrheal urethritis, is of little value in the treatment of gonorrheal uveitis. Sulfanilamide has also proved unsatisfactory in other forms of uveitis.

If obvious infection of teeth, tonsils, or accessory nasal sinuses is present, I prefer immediate eradication of the foci if this is practicable, anticipating improvement in the eye following whatever general and focal reaction may take place. I have never seen any unfavorable focal reactions, although I know that they have been reported (Berens²). If improvement fails to appear, then foreign protein therapy is started. Others prefer to start foreign protein therapy immediately, before eradicating the foci of infection.

If chronic nonspecific prostatitis alone is found, foreign protein therapy and prostatic massage are prescribed. If chronic cervicitis alone is found, foreign protein therapy and subsequent autogenous vaccine therapy are given. Autogenous vaccine may be made from cultures taken from any focus of infection (Berens²).

Formerly, it was generally believed that the production of shock was necessary for the efficient employment of foreign protein therapy. The height of the fever produced and the increased leukocytosis were regarded as indications of the effectiveness of the treatment. The milder foreign proteins, milk, and proteins of milk were supplanted by the more positive reaction-producing agent—intravenous typhoid vaccine.

The initial dose of intravenous typhoid vaccine varies from 25,000,000 to 60,000,000 killed bacilli. For safety, an intradermal skin test is first given and, if no reaction takes place within thirty minutes, the intravenous injection is given. The dose of subsequent injections is increased as is indicated by the reaction produced. The second injection is given after the temperature has returned to normal, which is usually the second or third

lay From three to ten injections are used, depending upon the need Others have recommended larger doses and shorter intervals between treatments

In 1935 A. L. Brown⁴ advanced the concept that protein injections produce their effect by a nonspecific "interfering" action of the specific antiprotein immune substances He pointed out that both specific and nonspecific antibodies were produced by foreign protein injections

Other foreign proteins have been used, such as diphtheria antitoxin and filtrates of pathogenic organisms Foreign proteins should not be used if the patient's general condition is poor because of fever, heart disease, or low vitality (Noe⁵ and Newton⁶)

Everyone is familiar with the sodium salicylate treatment as recommended by Gifford⁷—up to 1 gram of sodium salicylate per pound of body weight daily Large doses of salicylates by mouth are tolerated when given mixed with effervescent alkaline salts Pilocarpine sweats, combined with mercury rubs and iodides, have also been recommended Iodides alone in the later stages of subacute uveitis are valuable in hastening the absorption of the vitreous opacities

After the acute symptoms of uveitis have subsided, if the etiology is found to be syphilis, tuberculosis, or brucellosis, specific therapy should be started

The diagnosis of uveitis due to tuberculosis is not easy It must be made on the basis of clinical observations, and not on the basis of the tuberculin skin test, which may be negative Adler⁸ states that miliary tubercles with little inflammatory reaction may be seen in the iris by slit-lamp examination and in the choroid if the metastasis occurs shortly after the primary lesion has developed and before allergy is developed This may be found in young people of from 10 to 25 years of age Between 25 to 35 years of age the tubercular iritis is more inflammatory, synechiae form, and sclerosing keratitis may develop In the choroid, large greenish gray lesions, usually single and in the periphery, may be seen The vitreous humor is hazy and the skin sensitivity is often high

Patients from 30 to 50 show ciliary body involvement as well as iritis, and the process is highly exudative Mutton-fat deposits on the cornea are characteristic The skin reaction is usually positive

The treatment is that for general tuberculosis—fresh air, rest, high caloric diet, etc Brown⁹ believes that this is the most important measure Sodium gold thiosulfate has been

used in Europe and by Benedict⁶ Nonspecific syphilitic treatment has been used especially where the diagnosis is not certain

The specific treatment is tuberculin, which should be used in the allergic type of case but not in the tuberculosis-infected lesion in which it may produce injury (Eggston¹⁰) The initial dose should be one-tenth of the dose required to give a skin reaction

The perfolocal theory of tuberculin therapy regards allergy as responsible for local immunity and attempts to create local immunity by use of tuberculin Inactivity of the lesion is interpreted as attainment of local immunity, and the therapy is then stopped Blinded, phthisical eyes often result from this therapy

The desensitization concept sponsored by Woods¹¹ is based on the fact that allergy and immunity are unrelated Tuberculin is used for long periods, and the dose is steadily increased during periods of remission to maintain the desensitization Patients extremely sensitive to tuberculin must be treated cautiously with small amounts, being careful not to produce a local reaction It may be necessary to start with 0.000,001 mg or less The tuberculin therapy is discontinued only if the skin tests become almost totally nonreactive and the ocular lesion has remained nonreactive for a year or more Woods says that paracentesis causes an amazing improvement in these cases He also advocates the use of beta radium rays, which penetrate only 2 or 3 mm

Since these rays are obtained from radon, which is not available in Rochester, I have recently been using the superficial radiation from a new small therapeutic x-ray machine* whose rays approximate beta radiation in depth of penetration. A marked reduction in corneal vascularization results I have not yet determined the effect on lesions of the iris and ciliary body

Undulant fever (Malta fever) or brucellosis may be a cause of chronic uveitis Green¹² called attention to this in his paper before the American Ophthalmological Society in 1938 The disease is more widespread than is generally realized

The blood agglutination test for brucellosis is of value only when positive It is negative in 90 per cent of the chronic cases The skin test with intradermal injection of killed bacillary suspension gives a positive reaction in twenty-four hours, which may last three days or more and is often quite severe An opsonocytaphagic test is reported by Dr Green

*Picker portable x-ray machine with a capacity of 15 milliamperes and 50 kilovolts. We have used 40 kilovolts without a screen.

The treatment of brucellosis consists of sulfanilamide for the acute cases, prolonged artificial fever therapy, a serum for the acute and a vaccine for the chronic cases

In chronic uveitis there is not the need for haste as in acute uveitis, especially of the anterior type. Mydriatics should be used if there is local congestion or if there is a tendency to form posterior adhesions. If atropine sensitization occurs, duboisine $\frac{1}{1}$ to 1 per cent, hyoscine hydrobromide 1 per cent, or scopolamine 1 per cent may be used.

Cataract develops frequently in chronic uveitis, and little can be done to retard the development. A balanced diet with supplementary doses of vitamins B and C may help. Operation for cataract should be avoided for at least a year after the uveitis has quieted down, as determined by the cell content of the aqueous humor.

Of the rarer forms of uveitis, uveoparotitis, and uveitis with associated alopecia, poliosis, vitiligo, and deafness are mentioned. Their treatment is the same as for other forms of uveitis.

Summary

1. Acute uveitis requires active vigorous treatment to prevent posterior synechia and to reduce the intraocular inflammation.

2. Foreign protein therapy is the most valuable therapeutic measure in acute uveitis. The method of "shock" therapy and the Brown method based on the immune bodies "interfering" action, combined with anterior chamber drainage, are mentioned.

3. Various treatments for nonspecific uveitis are given.

4. The specific therapy of uveal tuberculosis, syphilis, and brucellosis is outlined.

5. The treatment of glaucoma, which may complicate both acute and chronic uveitis, is mentioned.

6. A secondary cataract complicating chronic uveitis should not be operated upon until the eye has remained quiet for one year.

Discussion

Dr Conrad Berens, *New York City*—Dr Gipner's paper is most important from the standpoint of the prevention of blindness, because, if the treatment of chronic uveitis was more specific, much of the unnecessary blindness occurring in adults would be eliminated.

I am glad that Dr Gipner spoke of subconjunctival injections of epinephrine, for I have found them most efficacious, especially when combined with $\frac{1}{100}$ grain of atropine. This method of treatment has often been successful when other methods have failed. In producing dilatation I have also found that the combined use of several cycloplegics seems to be effective. Sometimes the insertion of a row of homatropine and cocaine disks ($\frac{1}{100}$ grain each), at the same time that atropine and hyoscine are used locally, is useful. The use of a local anesthetic seems to enhance the action of these drugs.

I have found infrared rays useful in relieving pain in acute inflammations of the uveal tract, whereas diathermy sometimes seems to be contraindicated. Thermolite seems to be as efficacious as diathermy.

The management of these cases when tension is high is important, in my hands the use of 1 per cent homatropine and 1 per cent cocaine alternated with the use of weak solutions of pilocarpine sometimes controls the tension. Since using aspiration, instead of paracentesis, which does not frighten the patient so much as the thought of an operation (because we say we are only giving a hypodermic injection), I have been more satisfied with the management of hypertension in the presence of uveitis. If it becomes necessary to perform an iridectomy, I usually excise a small piece of sclera with a scleral punch, in spite of the fact that the wound usually heals, for in some cases prolonged filtration has been obtained.

I have also found artificial fever therapy of value if the gonococcus is present, and I believe sulfanilamide may also be used. It was apparently beneficial in 2 patients with chronic uveitis, suspected of being caused by prostatic gonorrheal infection. If the findings of Van Slyke and Mahoney¹ are accurate, sulfanilamide should be more valuable after a certain amount of natural immunity to the gonococcus has been developed.

The question of chemotherapy with sulfanilamide has been broached, and from our experimental work it would seem as though staphylococci also might produce uveitis. Therefore, we would have to consider sulfathiazole for the

¹ Van Slyke C. J., and Mahoney J. F. *New York State J. Med.* 40: 122 (1940).

treatment of these cases I used sulfathiazole in the treatment of 1 patient and obtained a severe general reaction without much improvement in the local condition. Likewise, I have been disappointed in the use of sulfanilamide in patients with chronic uveitis, supposedly caused by chronic sinusitis associated with streptococci and staphylococci infections, even when hemolytic streptococci were present. We realize that these drugs are bacteriostatic rather than bactericidal, and I believe that we should combine our treatment with immunologic therapy, since this combined treatment has apparently been shown by Fleming² to be more efficacious than immunotherapy or chemotherapy alone. I have also used neoprontosil subconjunctivally in these cases, but the evidence of the effectiveness of the treatment is inconclusive. Moreover, from what we know of this drug, one would not expect it to be effective unless it first reached the blood stream.

The question of the immediate elimination of foci of infection is an important one, and so long as there is improvement in acute inflammations I usually prefer to postpone radical elimination of these infections. I have observed not only severe acute exacerbations of the eye inflammation but also severe heart lesions in 2 patients. This opinion is in accord with that of Illingworth³ in removing tonsils in nephritis. However, I have apparently seen rapid recovery of acute uveal inflammation following the removal of a tooth.

Dr. Gipner raised the question of the use of autogenous vaccines and toxic antigens. We usually use autogenous toxic antigens and, in addition to antigens prepared from staphylococci and streptococci, we have recently found that 30 per cent of our patients with serious involvement of the uveal tract have had coliform bacilli in the upper part of the respiratory tract. Attempts to immunize rabbits against coliform bacilli apparently were successful. The immunity produced may be only partial in some rabbits and transitory in other rabbits. Some of our patients with chronic eye lesions apparently have been benefited by desensitizing doses of these toxic antigens, used over a long period of time in small doses similar to those used in tuberculin therapy. We found that with these bacteria acute iridocyclitis can be produced in rabbits with one-tenth the dose of bacteria required to produce iritis with iritis-producing streptococci.

For many years I have advocated the use of typhoid vaccine in preference to other forms of nonspecific protein therapy, and I believe that it is one of our best nonspecific methods of treating acute eye lesions. The danger of serious compli-

cations, even death, should not be overlooked, especially when using intravenous injections. It seems to me that a safer method is to administer the typhoid vaccine subcutaneously rather than intravenously. I have used Brown's method of employing typhoid H antigen and still am not sure whether nonspecific treatment enhances the curative effect of simple aspiration or paracentesis.

Concerning the treatment of tuberculosis of the uveal tract, I long ago pointed out⁴ that possibly ophthalmologists were relying too much on the virtues of immunology and had paid too little attention to mental and physical rest and to the use of natural and artificial sunlight as therapeutic aids. If tuberculin treatment is to be given, especially if the lesions are close to the macula, I believe that it should be instituted without an intradermal test, using a minute dose because I know of four eyes that became blind after merely testing the patient with tuberculin. In treatment, the dose that Dr. Gipner prefers is one-tenth of the amount used to produce the skin reaction. In recent years I have used a Vollmer patch test which seems to be about as sensitive as the intradermal test with the weaker purified protein derivative. The desensitization concept of treatment, originally sponsored by Wilmer,⁵ is the one that I favor not only for the use of tuberculin but also for the use of toxic antigens of other bacteria. In the treatment of tuberculosis of the eye my results have apparently been better with the use of bacillus emulsion.

I am most interested in Dr. Gipner's remarks concerning the use of beta rays but have had no experience with them.

Concerning the removal of cataracts in this group of patients, I think that ordinarily it is well to wait for a year following the subsidence of signs of inflammation as seen with the slit lamp, but sometimes these eyes exhibit slight postoperative inflammation. Even though the eyes do not appear unusually congested, a 1 per cent solution of holocain should be instilled into the conjunctival sac of each eye and the reaction compared.

We have made skin tests with Brucella abortus antigen in 39 patients who had inflammatory eye lesions, the majority of which involved the uveal tract. A positive reaction was obtained in 1 patient with choroiditis. Agglutinations with Br. abortus in 43 patients and with Br. melitensis in 5 patients were negative. Our ideas are in accord with Dr. Gipner's concept of diagnosis and treatment, but, since raw milk is used upstate and not in New York City, this probably accounts for the low incidence of uveitis from this cause which our findings seem to indicate.

Case Reports

BILATERAL ABDUCENS PALSY FOLLOWING LUMBAR PUNCTURE

BERNHARD DATTNER, M.D., and EVAN W. THOMAS, M.D., New York City

REACTIONS following spinal punctures are well known. Davenport¹ recently reported an incidence of 32.8 per cent moderate or severe reactions following lumbar punctures performed in the Board of Health clinics of New York City. The usual symptoms include headache, nausea, vomiting, and dizziness, and they may last from one to twenty-one days. Rarely, more serious accidents have been reported. These have been chiefly palsies of the extraocular muscles, most frequently the sixth nerve. Not more than 100 such cases have been reported in the literature and most of them have followed spinal anesthesia. Bilateral involvement of cranial nerves is rare, and so far as we know not a single case of bilateral abducens palsy following a simple diagnostic spinal puncture has been reported. Therefore, we believe that the following case is of unusual interest.

Case Report

A 36-year-old white man, born in Greece, was admitted to Bellevue Hospital on January 22, 1940. He gave a history of having had a penile sore in 1922 which was not treated. In 1929, following a positive blood Wassermann reaction, he received twelve hip and six arm injections from a private physician. From 1932 to 1933 he had irregular treatment for syphilis at a New York City Board of Health clinic. During this time he received eighty-eight bismuth and thirty-eight arsenamine injections. His blood Wassermann reaction was always strongly positive. In July, 1937, the first spinal puncture was performed. Following this he had severe headaches and was bedridden for four days. At that time his physical examination revealed no neurologic abnormalities. His spinal fluid Wassermann reaction was 1 plus. No cell count was recorded, but the Pandy test was reported as 1 plus and the Colloidal Gold curve as negative. For six months prior to his admission to Bellevue Hospital he had been receiving irregular treatment with mercury, the last injection having been given two months before entering the hospital. On January 9, 1940, at 1:00 P.M., a second lumbar puncture was done at one of the New York City Board of Health clinics. The report of the spinal fluid withdrawn at that time was as follows: Wassermann, 2 plus; Pandy, 1 plus; Colloidal Gold negative. No cell count was done. At 11:00 P.M. on the day of his spinal puncture he became nauseated and had a severe headache. He remained in bed for the next few days but in spite of this began to vomit on the third day after the tap. He had no fever or bladder disturb-

ances. On January 16, one week following the tap, he noticed double vision. He also complained of dizziness at this time although his headache was less severe. On the following day, January 17, he returned to the Board of Health clinic because of his diplopia. There the bilateral abducens palsy was diagnosed, and he was referred to Bellevue Hospital on January 22. A physical examination revealed no abnormal neurologic findings except the bilateral sixth nerve paralysis. The pupils were round and equal and reacted promptly to light. All tendon reflexes were present and equal. There were no signs of meningeal irritation or of pyramidal tract involvement and no sensory disturbances, including vibratory sense. On January 23 a cisternal puncture was done with the withdrawal of about 10 cc of clear spinal fluid. The Wassermann reaction of the fluid was reported as 4 plus in 1 cc., 4 plus in 0.5 cc., and negative in 0.1 cc dilutions. The Pandy test was negative as was the Colloidal Gold curve, and no cells were found. Following the cisternal puncture this patient stated that his headache, which had been steadily improving, disappeared entirely, and his only complaint was diplopia. Examination by an ophthalmologist on January 31 showed that the right eye could move 2 mm beyond the midline, whereas the left eye showed an inward deviation of 1 mm. On February 29 an examination revealed a lateral movement of the right eye of 6 mm as opposed to the normal 10 mm. The left eye showed a lateral movement of only 3 mm. Complete recovery had occurred by April 4.

Comment

The fact that the patient had syphilis must be considered before suggesting that the lumbar puncture was responsible for his bilateral abducens palsy. It is well known that syphilis can cause extraocular palsies. Uthoff² has recorded 27 cases of unilateral and 6 cases of bilateral sixth nerve palsies due to neurosyphilis, but the assumption that our case can be explained on this basis does not seem justifiable because there were no other neurologic signs of meningovascular syphilis, either subjective or objective, and the spinal fluid, though showing a moderately positive Wassermann reaction, had no other evidences of activity. Furthermore, there was a spontaneous recovery, as occurred in most of the cases reported following spinal taps. Consequently, it is logical to assume that the spinal puncture was responsible for the temporary palsy in this case. In explaining the mechanism that finally leads to such serious consequences, we have to consider the following facts that are known to be associated with reactions following spinal taps:

1. Headaches following lumbar punctures

From the Department of Dermatology and Syphilology, New York University College of Medicine, and the Department of Dermatology and Syphilology, Third Medical Division (New York University), Bellevue Hospital.

occur more frequently in individuals who have a normal spinal fluid than in those whose fluids indicate some pathologic processes in the central nervous system. This difference is striking from the statistics given by Davenport. There are, however, individuals who are peculiarly intolerant to spinal taps, e.g., neuropathics and cases of multiple sclerosis.

2 The headaches seem to be increased in severity by withdrawing large amounts of spinal fluid.

3 Most reactions have an incubation period of at least some hours and occasionally as long as two days.

4 They can be relieved by the horizontal position.

5 They are rare following cisternal punctures.

Neither the theory of meningeal irritation or spinal fluid leakage are in themselves satisfactory explanations of these facts. A meningismus alone cannot explain why the headaches are less severe when the patient is in a horizontal position, nor can it explain the absence of headaches following cisternal puncture or the fact that the severity of headaches seems to be influenced by the amount of spinal fluid withdrawn. Nevertheless, it is a known fact that a sterile meningitis, characterized by an increased cell count, may occur following both lumbar and cisternal punctures. Such cases have been frequently reported in the literature, recently by Hurxthal³ and by Reynolds and Wilson,⁴ and they have been observed by us on numerous occasions. The fact that reactions after spinal taps occur less frequently when some meningeal pathology is already present seems to favor the theory that meningeal irritation may account for some of the symptoms. The observation that many fewer reactions are encountered following punctures with thin needles than when ordinary sized needles are used can be offered in support of both the meningismus and leakage theories, but it does not explain in any way the absence of reactions following cisternal punctures, if the former theory is accepted.

On the other hand, the leakage theory cannot satisfactorily explain occasional reactions following dry taps or the use of fine needles. But even though leakage occurs, to explain the headaches we must assume that large amounts of spinal fluid are lost. There is no proof that this occurs or that the leakage lasts long enough to account for the incubation period, which may be of even two days' duration. But in favor of this theory is the undeniable fact that reactions following cisternal punctures are extremely rare. This is best explained by the fact that in the upright position there is a negative pressure in the cisterna magna whereas there is an increased pressure in the lumbar region.

Thus, while neither meningeal irritation nor leakage of spinal fluid can satisfactorily explain reactions to lumbar punctures, both factors may

be present and neither can be dismissed entirely. It is probable that both help to produce changes in the hydrodynamics of the central nervous system and that reflex responses of the vasomotor system have an important part in effecting such alterations. This can account for the period of latency in symptoms following spinal taps. We know that individuals vary in their symptomatic response to alterations in intracranial pressure, and it is reasonable to believe that the hydrodynamic changes following spinal taps vary in onset, duration, and intensity in different individuals. In some cases there may actually be an edema of the meninges or brain itself which brings pressure on vulnerable structures at the base of the brain.

That the sixth nerve should be the chief sufferer in such reactions is not surprising, because the frequent incidence of abducens palsies in comparison with other cranial nerves is not confined to accidents following spinal taps. They have been noted in toxic, infectious, and mechanical injuries to the central nervous system, e.g., spinal anesthesia, botulism, diabetes mellitus, suppurative and nonsuppurative infections of the meninges, vascular lesions, neoplasms, and trauma. This peculiar vulnerability of the sixth nerve is due to its anatomic position.⁷ It has a long and devious course, part of which is situated within Dorello's canal, which is frequently anomalous and varies in size and length. Furthermore, the nerve lies close to the dura throughout much of its course and is subject to pressure from all types of meningeal pathology or increased intracranial pressure. The majority of abducens palsies reported are found in the Italian literature. This may possibly be explained by the more or less characteristic cranial structure of the Mediterranean peoples. It is also noteworthy that the left abducens nerve is much more frequently involved than the right. In our case, both nerves were affected but the right improved more rapidly.

In taking all of the foregoing factors into consideration, the accident to the abducens nerves in our patient is best explained as part of his reaction to the lumbar puncture. To account for the interval of seven days between the spinal tap and onset of paralysis, we must postulate an increasing pressure on both nerves, but this is a reasonable deduction from our knowledge of lumbar puncture reactions in general.

Two other possibilities may be mentioned in explanation of the phenomena described. The first is that of a latent virus infection activated by the trauma of spinal puncture. This is pure speculation and has nothing in its support beyond the fact that the central nervous system seems to be subject to virus diseases that are still obscure and that do not necessarily cause a pleocytosis. The second is the possibility that there was a hemorrhage in the nuclei of both nerves. Quincke,⁸ who first performed spinal punctures, reported such autopsy findings in the region of the

nuclei of the third and sixth nerves following spinal tap in 1 case. Since Boehne⁶ has shown that the nuclei of the sixth nerves are supplied by two small arteries, known as the arteriae medianae, which arise from the basilar artery, a vascular lesion might account for the palsies in this case. But in the absence of any damage to closely adjacent structures such as the parabrachial or facial nuclei and facial nerve fibers, this seems most improbable. Therefore, the best explanation is a bilateral nerve trunk injury due to changes following lumbar puncture.

Summary

1. A seropositive syphilitic patient in the late stages of the disease, with an inactive spinal fluid

except for a mildly positive Wassermann reaction, develops a bilateral abducens palsy on the seventh day following a diagnostic spinal tap with spontaneous recovery.

2. Various possible explanations for such an accident are discussed.

DEATH FOLLOWING THE USE OF SODIUM IODIDE AND DIODRAST

T H SHANAHAN, M D, Jamestown, New York

ON DECEMBER 21, 1939, C. R., a white man, aged 49, was admitted to the hospital with complaint of urgency and frequency of urination for six weeks. He was passing pus and blood in the urine, voiding every half hour.

The patient was nervous and uncooperative. Under gas anesthesia, a cystoscope was passed, but because of the markedly inflamed bladder the ureters could not be identified. The patient had a large diverticulum on the left side in the region of the left ureter. After washing out the bladder several times and freeing it of considerable pus, we discontinued the operation.

The next morning a catheter was inserted, and the bladder was filled with 12 per cent sodium iodide. Cystograms were taken which showed a large diverticulum almost the size of a grapefruit on the left side.

The bladder was then irrigated with distilled water. During the irrigation the patient complained of considerable pain in the bladder region. Thirty cubic centimeters of diodrast was injected intravenously, taking five minutes to inject.

The patient did not show any immediate reaction but still complained of pain in bladder region. Pyelograms showed a large left ureter about 1 inch in diameter and a hydronephrotic kidney on the left side.

One hour after being put to bed the patient became cold and clammy and still complained of pain in bladder region. Heat was applied, and morphine (1/4 grain) was given with slight relief. The patient vomited several times. By 4:00 P. M. the patient appeared to be in moderate shock and complained of excruciating pain in the bladder region with tenderness over the bladder. Fearing that he might have a ruptured diverticulum, I opened the lower abdomen over the bladder under local anesthetic and found the bladder and diverticulum intact with no leakage of diverticulum.

The patient continued in shock and died twenty-four hours after the dye had been given.

A complete autopsy was not obtained, though we were given permission to explore the pelvis. The bladder and diverticulum were removed intact. The mucous membrane of the bladder was much inflamed. The lining of the diverticulum was darkly colored, almost as though it had been painted with tincture of iodine.

There have been several deaths reported from time to time following the use of diodrast intravenously. In most of these cases symptoms of shock began immediately. The Mayo Clinic reports 25,000 intravenous diodrast injections without a death. Dr. E. J. Foley, of Winthrop Chemical Company, the manufacturer of diodrast, reports that this drug has been used three to five million times.

The diodrast used in this case was the 30 per cent solution, though Rohb and Steinberg have used a 70 per cent solution in 456 cases—for taking pictures to show the chambers of the heart—without a single fatality.

It is difficult to say whether the sodium iodide injected into the bladder caused or contributed to this man's death or whether the diodrast injected directly into the circulation caused his death. The blood supply to a diverticulum is poor, so absorption from here should be slow. The bladder was immediately washed out, therefore, he did not absorb much from that source.

I believe that this man was allergic to iodides, although he did not give any definite history of such.

I believe patients should be questioned as to allergy before being given iodides in large amounts.

100 East 4th Street

SOFT TISSUE CALCIFICATION IN ACRODERMATITIS CHRONICA ATROPHICANS

ROBERT LEWIS NITKIN, M D, Jamaica, New York

THE presence of calcification in the soft tissues in acrodermatitis chronica atrophicans has not as yet been reported. In reviewing the literature no reference to this has been made.

The following case has been studied and presented before several dermatologic groups, including the Brooklyn Dermatological Society, and the diagnosis of acrodermatitis chronica atrophicans was confirmed.

The most interesting and striking aspect of the case is the roentgenologic findings of the upper and lower extremities.

Fig 1 shows both lower extremities with diffuse and extensive, soft, tissue calcification. The deposits are irregularly shaped but have a tendency to be laid in linear fashion. Some nodules can be demonstrated. This calcification is situated in the skin and subcutaneous tissues rather than in the deeper structures such as the muscles. It extends from the lower third of the thighs to the ankles but is most marked from the knees down. The osseous structures are of normal character for the patient's age (70).

Fig 2 reveals several, small, calcified nodules in the subcutaneous tissue on the posteromesial aspect of the right elbow. The largest nodule is about 2 mm in diameter.

Radiographic examinations of other regions show similar deposits over the lateral borders of the greater trochanters. The skull and sella turcica are essentially negative. The hands disclose hypertrophic osteoarthritis. A teleroentgenogram reveals exaggerated hilar markings and a tortuous aorta with calcified areas in the upper portions of the descending aorta.

Case Report

F B, a white woman, aged 70, housewife, Russian born, was admitted to the hospital on April 2, 1936, with a history of a complete right paralysis of the body for two years. Familial history was essentially negative.

Her dermatologic status dated back to the time of the birth of her second child forty years before. At that time she noticed that the skin of her lower extremities was rather dry. This was followed by redness of the skin and edema. This process slowly spread up the leg from the ankles to the hips. The swelling then gradually disappeared and left erythematous patches. Several years later the patient noticed diffuse, small, painless, hard nodules throughout the lower extremities, which slowly became larger but had, however, remained stationary in size for the past ten years.

The patient's main complaints were referable to the cardiac and circulatory systems and it

was for these reasons that she was admitted to the institution.

Physical examination at time of admission revealed a complete, right hemiplegia. Lung fields were negative. The heart was enlarged to the left and the sounds were irregular but of fair quality. The aortic second sound was accentuated and a pulse deficit was elicited. Her blood pressure was 142/90. The liver was enlarged to two fingers below the costal margin and was not tender.

The lower extremities from the hips down showed erythematous patches with associated cigarette, paperlike atrophy, edema, and telangiectasis. The anterior surfaces had infiltrative areas, sclerodermal-like in nature, which were surrounded by erythema and atrophy. The infiltrated patches were white, adherent to the skin and moved with it. Numerous, hard, shotlike nodules, movable in the subcutaneous tissue, were palpable from the ankles to the hips, but mostly in the upper two-thirds of the legs.

The right elbow on the ulnar surface possessed similar nodules, somewhat deep in the skin but, nevertheless, in the subcutaneous tissues. They, too, were hard and sharply demarcated.

During the patient's stay in the hospital over a period of four years, no definite clinical or roentgenologic changes were observed in her dermatologic condition. She did, however, experience several cardiac attacks and renal infections. In January, 1940, she made exitus on a vascular basis.

Laboratory examinations were essentially negative.

A necropsy of skin of the lower extremity disclosed the following microscopic examination—the epidermis was atrophic and consisted of two to four layers of cells. No distinct

FIG 1 Soft tissue calcification in acrodermatitis chronica atrophicans.

FIG 2 Soft tissue calcification in *acrodermatitis chronica atrophicans*

basal row was present. There was a moderately wide layer of surface keratin. The collagenous bundles of the corium had undergone degeneration to a marked degree and took the bluish stain. There was a minimal, lymphocytic infiltration with dilated but empty capillaries. There was edema of the entire corium and the subcutaneous fatty tissue was unchanged. No hair follicles were observed, but definable coil glands were present. Deep in the subcutaneous tissue were discrete, large masses of fibrous tissue, which in the central portion were being replaced

by calcific infiltrate. The larger arteries showed a nodular, subcutaneous thickening.

Summary

A report is made of the first case on record of *acrodermatitis chronica atrophicans* associated with soft tissue calcification, demonstrated in both the lower and upper extremities by roentgenologic studies and verified by necropsy and pathologic examinations.

90-10—149th Street

INFECTIOUS MONONUCLEOSIS

An Unusual Case

ARTHUR J. PHILIP, M.D., Rockville Centre, New York

ONE of the all-too common problems that the general practitioner meets in his everyday private practice, where extensive laboratory work is often a financial burden, is the unexplained fevers. One often sees these cases that one would like to hospitalize in order to remove them from the classification of "pyrexia of unknown etiology," or "ephemeral fever" but the financial burden is often too big for the family to bear.

This case is reported as an example of pathology in which a fairly common disease assumed so unusual a picture that it could not be diagnosed without some laboratory work, yet in which, at a minimal expense, the complete picture was revealed and the case report closed with a definite diagnosis.

Case Report

H. D., a white male youth, aged 21, was first seen on September 19, 1940, presenting as a chief complaint mild pain in the lower abdomen and a moderate fever (101 to 102 F) of five days' duration.

His past history was not remarkable. The usual childhood diseases had been encountered before the age of 5. He had had no medical treatment from this time until the present ill-

ness, except about five years ago when he had a contusion of the back.

The family history is irrelevant. There is no evidence of any familial diseases.

The present illness started five days before with a chilly sensation, nausea, malaise, and a temperature of 101 F by mouth. The abdominal pain that centered around the umbilicus, was mild and constant and bore no relationship to food. The symptoms persisted for four days more, with mild fluctuation of temperature up to 102 F accompanied by anorexia.

Physical examination revealed a moderately obese, young man, lying in bed apparently acutely ill. His temperature was 101.4 F by mouth, pulse, 88, and respirations, 22. The scalp and hair were normal, the ears were clear. The pupils reacted to light and accommodation. There was no discoloration of the conjunctiva. The mouth and throat were negative. There was no nuchal rigidity. Neither the thyroid nor any other glands of the neck were palpable. The heart sounds were of good quality and free of murmurs. The blood pressure was 118/71 in both arms. The lungs were clear throughout. The extremities revealed no abnormalities, no axillary or inguinal glands were felt.

The abdomen was somewhat difficult to examine because of the obesity of the patient.

The liver and spleen were not enlarged, no masses were felt. The gallbladder was not tender. At McBurney's point there was a slight degree of tenderness on deep pressure, but no muscle spasm was demonstrable. Rectal examination was negative.

Laboratory Examination—The urine was free of sugar, albumin, acetone, pus, or casts. The red blood cell count was normal. The white blood cell count cast the first ray of light on this otherwise negative picture. The total white cells numbered 6,700 with 36 per cent neutrophils, all of which were segmented. There were 58 per cent lymphocytes of which 16 per cent were large and 42 per cent small. There were 5 per cent monocytes and 1 per cent eosinophils. This picture was that of lymphocytosis, the cause of which was still in doubt. An aleukemic leukemia of the lymphocytic type had to be considered. Two days later the white count had increased to 10,500 with a further depression in the neutrophils to 20 per cent, of which 19 per cent were segmented and 1 per cent was of the band type. The lymphocytes had risen to 77 per cent, 63 per cent of which were small and 14 per cent large. No lymphoblasts were noted. Monocytes were 2 per cent and eosinophils 1 per cent. In spite of the fact that this was clinically not a case of infectious mononucleosis, a Paul and Bunnell test for heterophil antibodies was done and was strongly positive (4 plus) in a 1:256 dilution. The diagnosis, of course, was now obvious. As far as the literature will reveal there is no condition other than

infectious mononucleosis that will produce a strong heterophil antibody test.

The temperature fell by lysis. The abdominal pain gradually decreased and one week later the patient had completely recovered. However, at that time the white blood cells showed a count of 9,800 with still only 28 per cent neutrophils, all of which were segmented, and 60 per cent lymphocytes, of which 42 per cent were small, 17 per cent large, and 1 per cent lymphoblastic. The monocytes had increased to 9 per cent. Because of this blood picture the patient was re-examined. No liver, spleen, or lymph glands could be felt, though every possible site was examined.

Comment

This is undoubtedly a case of infectious mononucleosis but of such a negative picture that undoubtedly no accurate diagnosis could have been made without a white blood cell count and a heterophil antibody determination. All unexplained fevers, especially where there is a lymphocytosis, should have a heterophil determination done immediately whether or not the classic symptoms of lymphadenopathy and hepatic and splenic enlargement are present. Probably if this is done, the incidence of infectious mononucleosis would show an increase and unexplained fevers a decrease, since the patient runs a short febrile course and recovers promptly before much laboratory work can be done.

ADRENAL CORTEX CARCINOMA

Prevention of Postoperative Adrenal Insufficiency

MONROE E. GREENBERGER, M D, and JULIUS H. WINER, M D, New York City

A STORMY and frequently fatal postoperative course has occurred in a majority of the reported cases of adrenal cortex tumors. An unusually calm convalescence warrants presentation of the following case and emphasizes the value of adequate therapy to prevent development of adrenal insufficiency.

Case Report

Miss B. K., a white, single woman aged 25 was admitted to the Jewish Memorial Hospital on the urologic service of Dr. A. J. Greenberger, December 21, 1938, with evidence of hirsutism, amenorrhea, and voice changes. There were no remarkable features in her family history or past history except for irregularity of menstruation at three to five-month intervals since the age of 15.

There had been no menses during the previous eighteen months. During the preceding year the patient had noted visual difficulties, seeing spots in front of her eyes. Her voice became deeper and hoarser. An acneiform rash spread rapidly over the face, shoulders, and back and was resistant to the usual hygienic measures. Shortly thereafter, a profuse downy hair growth appeared on the face, becoming coarser and

blacker. This was followed by general growth of body hair, and the hair of the scalp became coarse and less curly. For the last six months, there had been intermittent dull right loin and lumbar area pain, and the patient had noted marked fatigue during the latter three months. She developed a troublesome headache and the lumbar pain became continuous and more severe during the week before admission.

On examination she appeared to be well developed and her voice was deep and hoarse. Her weight was 103 pounds (usual weight 110 to 125 pounds). She was 148 cm. in height with a foot-to-pubis measurement of 71.75 cm. and a span of 144.5 cm. There was marked coarse hirsutism of the cheeks, chin, lips, arms, and legs, with less profuse growth on the sternum and about the nipples, and the pubic escutcheon was typically a male one. The blood pressure was 122/88. The abdomen and the lumbar region showed no evidence of mass, tenderness, or muscle spasm. The labia minora and clitoris were distinctly hypertrophic. The hymen was intact and the rectal examination was negative.

Roentgen study of the thorax and skull were negative. The abdominal film showed the right kidney lower than normal, and excretory urography revealed a slight depression and compres-

FIG 1

FIG 2

sion of the right upper major calyx with slight kinking of the right ureter (Fig 1)

Films made after right perirenal insufflation (350 cc of air) revealed a large lobulated right upper quadrant mass above the right kidney (Fig 2)

Blood studies showed a normal white cell count and differential, with 5,310,000 red blood cells and a hemoglobin of 17.2 Gm. The bleeding and clotting times were normal. The Wassermann test was negative. Blood urea nitrogen was 13.3 mg per hundred cubic centimeters, sodium chloride, 510 mg, and sugar, 85 mg

The glucose tolerance test, the vaginal smears, and the routine urinalyses were negative. The basal metabolic rate was +12 per cent

Twenty-four-hour urine specimens contained less than 100 capon units of androgens per liter and would probably have shown less than 50 units per liter with further titrations. There was no excess anterior pituitary-like substance (less than 100 mouse units). The Aschheim-Zondek test was negative. The urine contained less than 100 mouse units of estrogenic substance per liter, the blood contained less than 200 mouse units of either anterior pituitary-like or estrogenic substances per liter. Bitterling tests showed at least 1,000 fish units of "ovipositor-lengthening substance" per liter, demonstrating "immense physiologic activity" of this urine. (The normal male output is 15 to 90 fish units per liter.) The synthetic androgenic and adrenal cortical preparations are among the more familiar ovipositor-lengthening substances.

A diagnosis of adrenal cortical neoplasm was made. For four days preoperatively, the patient was given 1 L of physiologic saline solution daily and 3 cc of adrenal cortex extract (eschatin) twice daily. Under avertin and cyclopropane anesthesia, a right oblique lumbar (usual kidney approach) incision was made with subperiosteal resection of the twelfth rib. A well-encapsulated mass, the size of a large orange, was exposed at the upper pole of the right kidney. Its pedicle was prominent, and the adrenal vein was found leading directly into the adjacent inferior vena cava. There was no evidence of vein involvement. The pedicle was clamped and cut and the stump was ligated. The tumor was removed *in toto*, without any evidence of infiltration of adjacent tissues. The patient received continuous infusion of saline and glucose during and after the operation.

Postoperatively, the adrenal cortical extract was continued in large doses (5 cc twice daily) for six days and then tapered off. She was given large amounts of saline and glucose by infusion and hypodermoclysis for three days postoperatively, followed by sodium chloride by mouth. After the third postoperative day she was kept on a low potassium diet. There was no immediate or delayed shock. The wound healed *per primam intentionem*, and convalescence was uneventful and complete in two weeks.

Pathologic Report (Dr. Angrist)—Macroscopic.—The mass measured 10½ by 4 by 5 cm and was reniform and of a reddish color. Its surface was glistening and its consistency was soft except for a firm area at one pole. The cut surface showed a dominant red-gray soft substance with some translucent yellow areas and patchy, cheesy appearing areas. The firm area at one pole was oval shaped and measured 5 by 2 cm. It was a gray-yellow color with a granular appearance and many septums.

Histologic Study—The tumor tissue consists of compactly arranged large cords and alveolar masses of closely packed epithelial tissue. The cells are quite polyhedral with distinct cell borders. The nuclei vary considerably in size and shape, and an occasional regular mitotic figure is found. In some areas the cord-like arrangement bears a distinct resemblance to the reticularis zone.

The cytoplasm is granular and pale staining. Some of the intervening tissue shows deeply staining eosinophilic cytoplasm. In the deeply staining cells, which suggest older altered cell groups, intense eosinophilic staining cytoplasm with some deeply eosinophilic granular material is noted. An occasional group of cells, with more pale staining and less compact cytoplasm, shows similar eosinophilic granules. A section of tumor shows the region of the capsule with invasion by tumor. Similar invasion of vascular channels is noted. Definite fuchsinophil characteristics are present. The diagnosis was encapsulated adrenal cortical carcinoma.

After the first postoperative month there was a recurrence of menstruation, with regularity for the first time in the patient's history. Her voice gradually became feminine in character. The hirsutism and the acne receded, and she became more active physically and mentally.

Immediately after operation the urine showed a low androgen output of approximately 2 to 3 mg., figure as androsterone. Nine months postoperatively the urinary androgen output was high (30 mg.), figured as androsterone (Dr. Marine). She began to show signs of recurrence of the tumor, such as amenorrhea, acne, and hirsutism over the face, back, chest, abdomen, and extremities. Subsequently, a nontender right midabdominal mass became palpable. The blood pressure became elevated to 184/128. The voice has become deeper. High-voltage roentgen therapy is now being given without evidence of response, but the patient is unwilling to be hospitalized for further investigation at present. Her poor prognosis is evident.

Roentgen studies of the chest and skeleton show no distant metastases (May, 1940).

That the calm postoperative course might have been due to metastases is contraindicated by the evidence of the low androgen output during the month after operation.

Comment

Weinberg^{1,2} found definite atrophy of the contralateral adrenal gland in 3 of his own cases and in a majority of thirty-four published reports where autopsy had been performed. This corroborates the premise of a postoperative adrenal insufficiency advanced by Walters and Kepler,⁴ Cahill and Loeb,⁶ and Goldzieher, Ingle and Kendall⁸ produced experimental "disuse" atrophy of the adrenal cortex in rats by giving large quantities of the adrenal cortical hormone, giving support to the hypothesis that the atrophy of the contralateral adrenal, in instances of adrenal tumor, is a "disuse" phenomenon resulting from excess hormone secretion by the opposite neoplastic gland.

The high percentage of recurrences noted in the literature suggests the advisability of avoiding any delay in diagnosis and therapy in this disease. As shown by Oppenheimer and Silver,¹⁰ the so-called "Cushing syndrome" may be a

true symptom-complex of adrenal cortical carcinoma. Diagnosis in these cases should be simultaneously directed toward the adrenals, since early localization and removal of an adrenal lesion will diminish the possibility of metastasis and will lessen the amount of atrophy of the contralateral adrenal. For similar reasons, operation for such a lesion should not be postponed in order to carry out numerous investigative and laboratory procedures.

Walters and Kepler⁴ and Marine³ stress the importance of preoperative and postoperative administration of adrenal cortex extract in *large enough* amounts, together with treatment to control the body *electrolyte balance* incidental to adrenal insufficiency. Weinberg suggests that implantation of pellets of the preparations for adrenal cortical replacement therapy may be possible.

This case shows that urinary androgen estimation is not of value in determining residual tumor or early metastasis, but it is valuable in diagnosis of subsequent development of a metastasis. The extreme malignancy of many of these tumors requires removal of the surrounding adipose tissue and blood vessels to eliminate, as much as possible, any extension or tumor metastases.

Summary

1 A case of adrenal cortical carcinoma is presented.

2 Acute adrenal insufficiency, following removal of the involved adrenal gland, may be prevented by administration of adequate adrenal cortex extract and electrolyte therapy.

3 Early and thorough operation is advisable to prevent progression of atrophic changes in the contralateral adrenal cortex.

We are indebted to Dr. David Marine, Dr. Abner Weisman, Mr. C. W. Coates, Dr. Howard Wesson, and the late Dr. David Perla for their hormone studies and assistance in the management of this patient.

Diagnosis

CLINICOPATHOLOGICAL CONFERENCES

FOURTH MEDICAL DIVISION OF BELLEVUE HOSPITAL

History

This was the first admission of a 38-year-old white waiter for occipital headache and malaise of ten days' duration. The past history was significant in that there had been a penile sore twenty years ago and a series of intramuscular and intravenous injections over a period of nine months during the past year. The present illness was preceded by a scratch from a pet cat about three weeks prior to admission to the hospital. About twelve days before admission the patient noticed that a nail in his shoe had caused a deep ulcer under the heel of his right foot. At Gouverneur Hospital an antiseptic and bandage were applied, and he was given 10 white pills of which he was to take 1 each day. On the following day he noticed the onset of a severe occipital headache that prevented his sleeping. His family doctor was summoned, and he prescribed for him 6 capsules containing pyramidon of which the patient took 4 during the next two days. He also took one-half of a small bottle of bromoseltzer. Five days before admission he noticed that his lips had become intensely cyanotic and his voice had become hoarse, but there was no dysphagia. The headache and cyanosis persisted until admission. The day before admission he was seen by an ambulance doctor who started to digitalize him, and he had received three cat units of digitals prior to admission.

On admission the patient was a well-developed, well-nourished man with intense bluish green cyanosis of the lips, nail beds, and skin, most marked on the face. There was no evidence of respiratory distress. The patient seemed slightly confused and disoriented. His temperature was 99.2 F, pulse, 120, respirations, 16, and blood pressure, 115/75. The head was negative. The pupils were normal and slightly irregular and reacted sluggishly to light. The fundi were negative. There was a catarrhal discharge from the nose. The ears were negative. Examination of the mouth revealed carious teeth, the tongue was clean and moist. The pharynx was moderately congested and there was a purulent postnasal drip. There was no nuchal rigidity or any palpable cervical nodes.

The heart was not enlarged to percussion, the point of maximum intensity was in the fifth intercostal space in the midclavicular line. There was regular sinus rhythm. The sounds were of good quality. A₂ and P₂ were equal and there were no murmurs. The lungs expanded equally, there were bilateral basal rales. There was some dullness at the right base posteriorly with diminished breath sounds. The abdomen, genitalia, and extremities were negative. The neurologic examination revealed absent deep reflexes in both legs and diminished deep reflexes in both arms. There was no Kernig or Brudzinski and no Babinski. The knee-to-heel and finger-to-nose tests were poorly executed. There was marked hyposensitivity to pain over the entire body with loss of testicular tenderness.

The patient's confusion rapidly changed to stupor and then to coma from which he was never aroused during his five days in the hospital. The cyanosis persisted and the respirations became more rapid and on the third hospital day changed into Cheyne-Stokes respirations alternating with periods of tachypnea and Biot breathing. The temperature remained below 101 F until death, at which time it rose to 102 F. The pulse was fast throughout the entire illness and rose terminally to 170. On the third day several small hemorrhages were observed in the fundi, and the patient developed several urticarial eruptions ranging in size from 1 to 5 cm with hemorrhagic centers on his arms and legs. A spinal tap performed on the fourth day yielded a crystal-clear fluid with a normal cell count. A cisternal puncture done postmortem yielded cloudy fluid on which no cell count was done. The patient was treated with sulfadiazine and digitals.

The laboratory findings were as follows. The urinalysis on admission was negative except for 1 plus albumin. On the day of death there was 3 plus albumin and 0-2 red blood cells per high-power field. The red blood count on admission was 5,200,000 with 100 per cent hemoglobin, the white blood count, 9,500 with 85 per cent polymorphonuclear cells and 15 per cent lymphocytes.

On the day of death the red blood count was 6,720,000 with 130 per cent hemoglobin, the white blood count, 15,800 with 79 per cent polymorphonuclears and 16 per cent lymphocytes. The blood Wassermann was negative. The nonprotein nitrogen was 50 and the blood sugar was 114. The carbon dioxide-combining power was 70 per cent. The blood was negative for methemoglobin. Agglutination tests for typhoid and paratyphoid were negative. The Felix-Weil test was negative. A spinal tap revealed a crystal-clear fluid, the cell count showed a few red cells, the Pandy was negative, the colloidal gold curve was 0012321100, initial pressure was 290 mm, pressure on the right jugular compression was 600 mm and on the left jugular compression was 350 mm. There was no evidence of block. A roentgenogram of the chest revealed a patchy pneumonitis throughout both lungs but of greatest density over the middle third of the right lung field. There was slight enlargement of the heart and marked accentuation of the pulmonary conus.

Postmortem culture of the cerebrospinal fluid taken from the meninges between the cerebral hemispheres yielded *Pneumococcus* type VI and *Staphylococcus aureus*. Culture of a seared specimen of lung grew out *Staphylococcus aureus*, *Streptococcus viridans*, and gram-positive bacilli. Samples of the cerebrospinal fluid drawn by cisternal puncture postmortem were sent to the Rockefeller Institute where cultures were entirely negative. The spinal fluid was injected into six mice. They all remained well until the nineteenth day when one of them was found dead. The brain of this mouse was found to be bacteriologically sterile and was passed to six normal mice which remained well. At the end of four weeks all of the mice of both passages were tested for immunity to lymphocytic choriomeningitis and were found to be susceptible. The cat was apprehended at our request by the American Society for the Prevention of Cruelty to Animals and was observed for two weeks at the Brooklyn Board of Health. It was reported to be a normal healthy animal in all respects.

Discussion

DR EMANUEL APPELBAUM. The outstanding clinical features in this case were encephalopathy, cyanosis, and pulmonary and cardiac signs. By far the most important signs and symptoms were those referable to involvement of the central nervous system, as shown by headache, clouding of the eyes, stupor, and

ing to stupor, pupillary changes, and absent knee jerks. The term encephalopathy may appropriately be used to describe these various manifestations. Permit me to enumerate the more important medical conditions that may cause some form of encephalopathy. These are (1) inflammations, which include meningitis, encephalitis, brain abscess, and cerebrospinal syphilis, (2) neoplasms, (3) cerebrovascular diseases and accidents, (4) blood dyscrasias, (5) metabolic and deficiency diseases, (6) intoxications due to drugs and chemicals, and (7) toxic reactions in the course of some systemic infection.

The possibilities that have to be considered in this case, it seems to me, are meningitis, encephalitis, cerebrospinal syphilis, drug poisoning, and a reaction associated with a general infection. While one postmortem culture of spinal fluid was reported as showing a *Pneumococcus* type VI and *staphylococcus*, another sample of fluid obtained from the cistern was entirely negative. Furthermore, the spinal fluid obtained during life showed no abnormalities except for a weak syphilitic colloidal gold curve. It should be noted also that there were no clinical signs of meningeal irritation. I am, therefore, inclined to rule out the possibility of meningitis. While the drug intoxication could not be regarded as the sole cause of his cerebral symptoms, which ushered in his disease, it might have been a contributory factor. There was no clinical or laboratory evidence to warrant a diagnosis of either rat-bite fever, which may rarely be conveyed by a cat, or of a general sepsis caused by the nail injury. More likely, the encephalopathy was due either to some form of encephalitis or to cerebrospinal syphilis, vascular type. It should be pointed out that the spinal fluid may be normal in encephalitis.

Another striking clinical manifestation was the intense cyanosis. The important causes of cyanosis are

- 1 Congenital heart disease
- 2 Cardiac failure
- 3 Pulmonary diseases
 - a Emphysema and asthma
 - b Pneumonia
 - c Tumors
 - d Fibrosis
 - e Pulmonary embolism and thrombosis
 - f Diffuse pulmonary arteritis (Ayerza's disease)
 - g Carcinomatous lymphangitis
 - h Thromboembolic obstruction

The cat was apprehended at our request by the American Society for the Prevention of Cruelty to Animals and was observed for two weeks at the Brooklyn Board of Health. It was reported to be a normal healthy animal in all respects.

Discussion

DR. EMANUEL APPELBAUM. The outstanding clinical features in this case were encephalopathy, cyanosis, and pulmonary and cardiac signs. By far the most important signs and symptoms were those referable to involvement of the central nervous system, as shown by headache, clouding of the sensorium, progress-

ing to stupor, pupillary changes, and absent knee jerks. The term encephalopathy may appropriately be used to describe these various manifestations. Permit me to enumerate the more important medical conditions that may cause some form of encephalopathy. These are (1) inflammations, which include meningitis, encephalitis, brain abscess, and cerebrospinal syphilis, (2) neoplasms, (3) cerebrovascular diseases and accidents, (4) blood dyscrasias, (5) metabolic and deficiency diseases, (6) intoxications due to drugs and chemicals, and (7) toxic reactions in the course of some systemic infection.

The possibilities that have to be considered in this case, it seems to me, are meningitis, encephalitis, cerebrospinal syphilis, drug poisoning, and a reaction associated with a general infection. While one postmortem culture of spinal fluid was reported as showing a *Pneumococcus* type VI and *staphylococcus*, another sample of fluid obtained from the cistern was entirely negative. Furthermore, the spinal fluid obtained during life showed no abnormalities except for a weak syphilitic colloidal gold curve. It should be noted also that there were no clinical signs of meningeal irritation. I am, therefore, inclined to rule out the possibility of meningitis. While the drug intoxication could not be regarded as the sole cause of his cerebral symptoms, which ushered in his disease, it might have been a contributory factor. There was no clinical or laboratory evidence to warrant a diagnosis of either rat-bite fever, which may rarely be conveyed by a cat, or of a general sepsis caused by the nail injury. More likely, the encephalopathy was due either to some form of encephalitis or to cerebrospinal syphilis, vascular type. It should be pointed out that the spinal fluid may be normal in encephalitis.

Another striking clinical manifestation was the intense cyanosis. The important causes of cyanosis are

- 1 Congenital heart disease
- 2 Cardiac failure
- 3 Pulmonary diseases
 - a Emphysema and asthma
 - b Pneumonia
 - c Tumors
 - d Fibrosis
 - e Pulmonary embolism and thrombosis
 - f Diffuse pulmonary arteritis (Ayerza's disease)
 - g Carcinomatous lymphangitis
- 4 Tracheolaryngeal obstruction

- 5 Obstruction of the superior vena cava.
- 6 Chest deformities
- 7 Respiratory failure in disease of the central nervous system
- 8 Alterations in the blood
 - a Polycythemia
 - b Methemoglobinemia and sulfhemoglobinemia (enterogenous cyanosis)
 - c Drugs

As will be discussed presently, the patient showed definite evidence of cardiopulmonary pathology. However, it is my belief that the intense cyanosis, which was sudden and recent, was due not to heart or lung disease but to acetanilid poisoning. It will be recalled that the patient took one-half a bottle of bromoseltzer, which contains a considerable amount of acetanilid. As you undoubtedly know, acetanilid is a benzol derivative, and poisoning with this drug is apt to cause marked cyanosis. Most instances of acetanilid poisoning are of the chronic form, following the use of the drug over a long period of time. In addition to cyanosis, these patients show depression and, finally, cardiac collapse and coma. Cardiac dilatation, even with murmurs, has been noted. A severe anemia, with many nucleated red blood cells, is not uncommon. The acute form of poisoning may follow moderate doses—as little as 10 grains. In such instances an idiosyncrasy is undoubtedly a factor. The collapse and cyanosis occur early in this form. Anemia is not a feature of the acute intoxication. The cyanosis, which may persist for weeks after the drug is stopped, is due mainly to the presence in the blood of sulfhemoglobin and paramidophenol derivatives. It should also be noted that the cyanosis is generally associated with anoxia, but the severity of the anoxia does not necessarily parallel the degree of cyanosis.

In this connection I would like to say a few words about enterogenous cyanosis. This is a chronic disease characterized by marked intestinal disorder—either diarrhea or constipation—clubbing of the fingers, and an intense cyanosis due to the presence in the blood of both methemoglobin and sulfhemoglobin, derived from products in the alimentary tract.

With regard to the patient's pulmonary condition, I believe that there was marked congestion and probably also a pneumonitis. The roentgenograms of the lungs would seem to support this belief. It is, however, dif-

ficult to say whether or not there was also a diffuse fine pulmonary fibrosis.

There is no doubt there was an enlargement of the right side of the heart. As you will note in the roentgenogram, the configuration is that of a cor pulmonale, in which the enlargement of the right ventricle follows hypertension of the pulmonary circulation. For clinical purposes cor pulmonale may be classified into primary and secondary. In the former the disease begins with enlargement of the right ventricle, while in the latter the right-sided heart failure follows a preceding left ventricular failure. The primary form, which is less common, may be either acute, subacute, or chronic. The acute cor pulmonale results from a sudden obstruction of the trunk or first branches of the pulmonary artery by embolism or thrombosis. There must be a sudden blocking of at least 60 per cent of the pulmonary circulation. In rare instances it may be caused by a sudden perforation of an aortic aneurysm into the pulmonary artery.

The chronic cor pulmonale is caused by mitral stenosis, chest deformities, pleural or pulmonary fibrosis, emphysema, and other chronic pulmonary conditions that cause an increased resistance in the pulmonary circulation. In rare instances it is caused by a primary pulmonary endarteritis, which has been ascribed to syphilis by Ayerza and others. The course of the chronic form is progressive and slow over a period of years.

In the subacute cor pulmonale there is a relatively rapid development of right ventricular enlargement and failure in a patient with no previous cardiopulmonary disease. The course ranges from two to eight weeks. It differs from the acute form by the more gradual onset and a slightly more prolonged course and from the chronic form by the absence of antecedent cardiopulmonary disease and by a much shorter course. As far as I know, the only condition that causes the subacute form is carcinomatous lymphangitis, metastasizing from a gastric carcinoma, usually scirrhus.

It is difficult to explain the cor pulmonale in our patient unless we assume that he had some pulmonary vascular disease or diffuse fibrosis. In summary, I believe that the patient had either encephalitis or cerebrospinal syphilis, pulmonary congestion and pneumonia and possibly a diffuse fine fibrosis, and an enlargement of the right side of the heart typical of cor pulmonale.

DR HENRY C. FLEMING. I seriously doubt

that this patient suffered from an acute manifestation of acetanilid poisoning. I do not believe that one-half of a small 10-cent bottle of bromoseltzer contains sufficient acetanilid to cause such a reaction.

In my opinion this patient suffered from a long-standing syphilitic disease of the central nervous system and the spinal cord—*tabes dorsalis*. The etiology of this encephalopathy is not clear but it may have been a virus.

DR. EDWARD H. REISNER, JR. It was originally thought that this case should be a medical examiner's case because of the history of acetanilid ingestion. However, the medical examiner who reviewed the case had never seen such manifestations from acetanilid poisoning and refused to autopsy the patient himself on the grounds that there was insufficient evidence that any drug had caused death.

DR. MENNASCH KALKSTEIN. I would like to raise the question, in view of the ulceration of the foot, as to whether or not tetanus might be the cause of the patient's symptoms.

DR. APPLEBAUM. The patient's clinical course was entirely different from anything resembling tetanus. I do not believe that diagnosis could be considered.

DR. A. WALTER FREIREICH. Did the patient receive tetanus antitoxin? While this is not the picture of tetanus, I believe there are a few cases on record of allergic reactions and encephalitis following the injection of tetanus antitoxin.

DR. REISNER, JR. As far as we know this patient did not receive tetanus antitoxin. The ulceration of the heel came from a nail on the inside of his shoe and was a long-standing chronic affair.

DR. MAX TRUBEK. I think that all the evidence here points to the diagnosis of an acute encephalitis due to a virus. There probably was old *tabes* and perhaps syphilis was present elsewhere. The cyanosis could have been caused by the bromoseltzer or the sulfonamide or by congestive heart failure. The terminal polycythemia was probably due to dehydration.

Pathology

DR. DAVID M. SPAIN. The anatomic interpretation of this case resolves itself into three distinct considerations. Anatomically, the symptoms and signs of this case are fairly adequately explained. However, in certain instances, the etiology of the pathologic changes is not quite clear.

At autopsy, the heart weighed 510 Gm and revealed a massive concentric hypertrophy of the left ventricular myocardium to such an extent that the interventricular septum bulged into the right ventricular chamber, thereby markedly reducing it in size and impinging considerably on the pulmonary outflow tract. There also was a moderate hypertrophy of the right ventricle. These findings explain the signs that were interpreted as caused by *cor pulmonale* during life. This method of causing signs of failure of the right side of the heart is sometimes known as Bernheim's syndrome and occasionally causes confusion clinically in the presence of hypertension. However, the cause of the cardiac hypertrophy is not clear. There were no congenital anomalies, no valvular damage, and only a minimal amount of arteriolar nephrosclerosis. The syphilitic aortitis caused only a minimal amount of anatomic change. Whether or not the patient at one time had had hypertension cannot be definitely ascertained at this time.

The neurologic findings consisted of two separate entities. The cord lesion was typical of *tabes dorsalis*.

On the other hand, the brain lesion appeared to be entirely unrelated to the syphilis and the cord lesion. On gross examination, the brain showed a marked hemorrhagic encephalopathy in the white matter of both frontal lobes. On microscopic examination, sections through the superior frontal gyrus stained for myelin sheath showed an acute disseminated leuko-encephalitis. There were many areas of early myelin degeneration throughout the white matter of this section. These areas were, for the most part, perivascular and were hemorrhagic, containing many cells filled with brownish pigment. The partially demyelinated areas contained a number of mononuclear cells. According to Dr. L. D. Stevenson, who examined the brain and the spinal cord lesions, the changes did not appear to be syphilitic in origin but were much more like the encephalitis caused by a virus infection.

Anatomic Diagnosis

Primary. Acute disseminated meningo-encephalitis.

Secondary

Heart. Massive concentric myocardial hypertrophy — left ventricle with bulging of interventricular septum into right ventricle.

Moderate myocardial hypertrophy—right ventricle
Aorta Syphilitic aortitis
Lungs Congestion
Liver Chronic passive congestion
Spinal Cord Tabes dorsalis

DR APPLEBAUM The postmortem, to my mind, does not adequately explain all the clinical features. The configuration of the heart as shown by the roentgenogram was certainly typical of cor pulmonale. Acetaminid poisoning has, of course, not been ruled

out. The encephalopathy is explained by the finding of a demyelinating form of encephalitis. Perivascular demyelination has been seen most frequently in postinfectious encephalitis but also has been observed recently in the Western equine encephalomyelitis. But it is difficult, if not impossible, to say whether or not a virus might have been transmitted through the cat's bite. I do not believe that this is very likely. It is unfortunate that the brain was not subjected to virus studies.

WOMAN'S AUXILIARY—ONONDAGA COUNTY

The Onondaga County Medical Society and its Woman's Auxiliary are planning a luncheon on Tuesday, September 23, 1941, at the Hotel Syracuse, Syracuse, New York, as part of the program of the regular Fifth District Meeting of the Medical Society of the State of New York.

An entertainment is being planned to follow the luncheon, and the doctors' wives as well as the doctors are cordially invited to attend this function. Reservations: Dr. Sabine, Little Falls, or Virginia B. Marty, 301 Summit Avenue, Syracuse, New York.

"SHOE LEATHER EPIDEMIOLOGY"

"Shoe leather epidemiology" in regard to tuberculosis case-finding is a term coined by Dr. Edward S. Godfrey, Jr., state commissioner of health, to emphasize the fact-finding work that needs to be done by physicians, nurses, and social workers in discovering the sources of infection, says *Health News*. Commissioner Godfrey's term has special significance in connection both with the campaign which he has officially launched for the substantial eradication of tuberculosis in upstate New York by 1960 and with the recent observance of the Fourteenth Annual Early Diagnosis Campaign conducted by national, state, and local tuberculosis and health associations in cooperation with the public health authorities.

"Shoe leather epidemiology," according to Commissioner Godfrey, "differs from 'swivel chair epidemiology,' which consists in attempting to solve a problem by prepared statistical tables, in that it means going out on the highways, byways, and alleys, walking the streets and climbing the stairs, or bumping over country roads, in order to ferret out the sources of tuberculosis infection and to find out what makes the statistics 'that way,' to find out what lies behind them, to find the vulnerable point for attack, and to find the source of infection."

"Tuberculosis is an infectious disease. It cannot be acquired unless a person comes in contact with tubercle bacilli. It is also an opportunist disease. The germ develops clinical tuberculosis in those persons who have the lowest resistance. Contributing to lowered

resistance, we usually find poverty and all of its allies, such as faulty nutrition, inadequate housing and sanitation, overwork, worry, strain, and acute illnesses.

"These allies of the disease need to be reduced to writing on the case history of the patient. If infection is present, then the correction of environment becomes almost as important as finding other cases because this guards against the spread of the disease and the breakdown again of the patient after taking the cure."

"Shoe leather epidemiology" means going from the home to the work place, to the school, to the associates, to all of the immediate contacts of the patient, adults especially, in order to find the source of infection. We are too prone to be satisfied if we line up the women and children contacts for examination. They are the easiest to reach. We must recognize and do also the harder job, the bringing to x-ray examination of the male adult contacts and those of advanced age, both men and women, among whom source cases are most likely to be found."

The object of the 1941 "E D C" is to employ every channel for informing the public that "A Good X-Ray Is Your Doctor's Best Aid in Discovering Early Tuberculosis." Commissioner Godfrey urges the department's headquarters and district staffs to utilize the campaign literature, posters, and other educational devices that are obtainable from the State Committee on Tuberculosis and Public Health of the State Charities Aid Association and its county and city tuberculosis and health associations.

Abstracts of Proceedings

of the

NEW YORK PATHOLOGICAL SOCIETY

REGULAR MEETING, FEBRUARY 27, 1941

JEAN OLIVER, *President*

JOHN M. PEARCE, *Secretary*

Studies on the Relation of the Kidney to Cardiovascular Disease Dr M C Winternitz (*by invitation*), *Yale University School of Medicine*

The clinical and anatomic changes that follow bilateral nephrectomy contrast sharply with those that result from the ligation of both main renal arteries. Moreover, the fulminating symptoms and the lesions that characterize the latter group are reproduced by an injection of extracts of kidney into the nephrectomized dog. This has formed the basis of an experimental study of the relation of the kidney to cardiovascular disease, with the following results to date:

The survival time after bilateral nephrectomy may vary from six to ten or more days. The electrolytes of the blood are influenced by the procedure, and elevation of serum potassium is associated with heart block. After a restricted potassium intake the survival time is prolonged, the potassium elevation is not significant, and death occurs with the blood nonprotein nitrogen at levels otherwise not observed.

The vasodepressor agent of kidney extract is easily removed. The vasopressor substance so far has not been separated from the necrotizing principle. It has been purified so that a content of 1 gamma of nitrogen per kilogram of body weight will raise the pressure of a dog with a typical and marked renin curve.

The necrotizing process involves heart muscle, diaphragm, and smooth muscle of vessel walls—both of arteries and veins—as well as that of the alimentary canal and other hollow viscera. Muscle necrosis frequently is associated with hemorrhage, but these two processes each occur independently. Moreover, there is some evidence that the two effects may be dependent upon different principles.

The lesions of the heart and blood vessel wall which follow the use of kidney extracts are rarely associated with superimposed thrombi. Those that result from extracts of

some other organs, testicle in particular, as a rule are complicated in this way. This is dependent upon the greater influence the latter extracts exert on the coagulation time of the blood and emphasizes the importance of clotting time as distinct from mural lesion in association with thrombus formation. Tolerance is manifested to increasing daily injections of kidney extracts by some animals, but this does not involve appreciable changes in either the vasodepressor or vasopressor effects. Such animals do not survive bilateral ureteral ligation for a longer period, but the hemorrhagic and necrotizing lesions are distinctly less extensive.

Moreover, preliminary experiments indicate that their serum tends to protect other animals against the necrotizing effects that follow the various experimental procedures now known to be associated with muscle necrosis.

Drs. Mylon, Katzenstein, and Waters have participated in this study.

Discussion

DR. HOMER W. SMITH (*by invitation*). Although Dr. Winternitz has not presented his results with any special reference to the Goldblatt experiment, they certainly bear upon the pathologic changes that accompany protracted renal ischemia, and I have been thinking of their physiologic significance in this connection. Certainly, we cannot conceive that these necrotizing and hemorrhagic cytotoxins are related to the normal function of the cardiovascular and renal systems, and it is pertinent to speculate concerning their origin.

The work of Neubauer, Krebs, and others has demonstrated that the process of deamidization of amino acids is an oxidative one—that is, amino acids generally are oxidized to keto acids. This process of deamidization is carried out by oxidative

deamidases in the liver, the kidney, the intestines, and other organs and requires a substantial oxygen tension. On the other hand, the investigations of Schuler and his co-workers, of Holtz, and of Kempner have demonstrated that in the absence of oxygen, or at low oxygen tensions, tissue decarboxylase can remove the carboxyl group from at least certain amino acids, leaving an amine. To what extent decarboxylase and oxidative deamidase are interdependent in the intact organ is unknown, but in *in vitro* experiments they can operate separately. In the absence of oxygen, aromatic amino acids such as tyrosine or phenylalanine can be decarboxylated with the formation of pressor and cytotoxic amines. Holtz and his co-workers have demonstrated that, under anaerobic conditions, kidney extracts produce the powerful pressor hydroxytyramine from the innocuous dihydroxyphenylalanine (dopa).

Dr R J Bing has carried this problem one step closer to our present subject by showing that when dopa is injected into, or perfused through, the ischemic cat kidney a powerful pressor substance, presumably hydroxytyramine, is thrown from the kidney into the systemic circulation.

Though the contribution made by the kidney to total deamidation is no doubt relatively small as compared with that of the liver, yet the concentration of oxidodeamidase per gram of tissue is from four to eight times higher in the kidney than in the liver. And it is not impossible that certain deamidations are so unequally distributed between the two organs that failure of the kidney in this respect could produce most malign results.

In view of the evidence I have just mentioned, one might explain the Goldblatt experiment as anaerobic decarboxylation, coupled with anoxic failure of deamidation of certain nitrogenous substances, though not necessarily tyrosine or phenylalanine, with the production of pressor and cytotoxic agents which wreak havoc with the cardiovascular system. There is, of course, no proof of this speculation at the present time, and I am quite unable to set into this frame renin or the renin-activator, angiotonin, and angiotonin-inhibitor system so well studied by Dr Page and his colleagues. But the view that the Goldblatt experiment and, indeed, the view that essential hypertensive disease in man represents a metabolic failure of oxidative deamidation of one or more substances important in intermediate metabolism has certain attractions. The local renal theory

if I may call it such, is not fully supported by our observations on the functional status of the kidney in subjects with essential hypertension, nor does the local renal theory explain genetic predisposition, the presence of hypertension in some subjects with nephritis and its absence in others, or the suggestive similarity between essential hypertension and pre-eclampsia and eclampsia, and the high incidence of essential hypertension in post-eclamptic statistics. A general theory of hypertension which encompasses renal ischemia as one, but not the only, etiologic possibility is perhaps a conservative rather than a radical interpretation. The crucial question to be answered is whether or not oxidative deamidation is the essential metabolic fault. If Dr Bing's experiment proves to be anything more than an exotic phenomenon involving one amino acid, I should not be surprised if it assumes considerable historic significance in this connection.

It is pertinent to this point that Dr Schroeder has been able to reduce blood pressure in rats with experimentally induced hypertension and in subjects with essential hypertension by means of tyrosinase. This is not a deamidase but an oxidase that oxidizes phenolic derivatives, and it is tempting to see Schroeder's tyrosinase promoting the oxidation of some compound such as the hydroxytyramine, which is presumably formed in Bing's experiment on the ischemic cat kidney.

All this is not too remote from Dr Winternitz's observations. Renal extracts must contain a variety of enzymes, coenzymes, and related substances which are capable, on intravenous injection into nephrectomized animals, of exerting cytotoxic effects. When the extracts are prepared from ischemic renal tissue there is the added possibility of undetoxified nitrogenous remnants of intermediate metabolism. The puzzling thing, no matter how one interprets the result, is the extraordinary toxicity of these extracts.

There is one question I should like to ask Dr Winternitz. If the arteriolar lesions of experimental and human hypertension are caused by humoral agents rather than by elevated pressure *per se*, why is the pulmonary bed immune? And why is the ischemic kidney, which is said to be "protected by the clamp," also immune?

DR IRVING GRAEF. I think I need not apologize for pointing with some pride to the fact that another strong fresh breeze of information on the subject of renal hypertension has come from the pathologists. Goldblatt,

a pathologist, gave a clearly substantiated and beautifully demonstrated experimental method for the production of chronic hypertension in animals. And now, from another pathologic laboratory, a fresh effort has resulted in the demonstration that in the mechanisms involved in experimental hypertension there is more than the production of hypertension, and there is more than the effect of hypertension. I think the chief contribution of Dr. Winternitz's tour de force lies in his dissociation of the effects of renal ischemia on the body. He has referred, in passing, to the central nervous system but has not detailed the special changes that may take place in the central nervous system in hypertension, even without renal ischemia. He has shown the high tropism of some of the substances which can be derived from the kidney, from the testis, and perhaps from other organs for smooth muscle. Without identifying these substances, finally, he has shown that changes in the organs which are encountered in the production of hypertension may be associated with some of the special vascular phenomena, some of the special blood alterations, and some of the changed metabolic processes. Dr. Smith has concerned himself with the finer details of the metabolic alterations which might be anticipated to occur in ischemic kidneys. Whether they occur in the normal kidney in the segmental manner or in an interrupted manner is something on which there is no information. Whether the normal kidney is concerned with the elaboration of substances that contribute to alterations in the vascular tonus is something to think about, though we cannot discuss it in any detail on the evidence available.

My concern with experimental hypertension has been to try to dissociate, if possible, among those animals that exhibit clean-cut evidence of hypertension, renal insufficiency and vascular disease. In a survey of the material furnished me by Dr. Irvine Page I have encountered three groups of animals: first, with little or no hypertension, though they have had renal ischemia. But with this finding of little or no hypertension there was a high degree of renal insufficiency and associated vascular lesions. In a second group we found the classic picture of the so-called malignant hypertension, with renal insufficiency, severe progressive hypertension, and disseminated vascular necrosis. As you may expect, there was a third group with severe acute hypertension with disseminated vascular disease and no definite evidence of renal in-

sufficiency. The common or garden variety of malignant hypertension constitutes the largest group, but these two other groups at either extreme suggest the dissociation pattern that Dr. Winternitz has offered. Certainly, it behooves us not to oversimplify this problem and assume that hypertension alone, renal insufficiency alone, or in combination is effective in producing this, that, or the other feature.

I have also been impressed by the fact that the vascular lesions in the dog are quite different in their distribution from the lesions found in man. In man, I think it is fair to say that one is impressed with the fact that the necrotizing lesions are below the diaphragm, in the splanchnic area, with involvement of the gastrointestinal tract and the genitourinary tract and not much else. Eye lesions are a positive exception; cerebral lesions are described occasionally. But one can search through the average case fairly minutely and grade the lesions according to distribution and find that they generally occur according to this pattern of major splanchnic involvement. I do not think the evidence in the dog throws any light on this particular problem. Coronary lesions are extremely rare in malignant hypertension in man and extremely uncommon in my dog material, although myocardial necrosis is extremely common. Therefore, I am not sure that the injury to the myocardial muscle is the same as the injury to the smooth muscle of the intestine or arterioles.

The eye lesions are most interesting. The eye lesions in the dog are different from eye lesions in man, as you might expect, for the vessels in the dog's eyes are different from the vessels in man's eyes. These differences concern the muscular coats, the presence or absence of elastic lamellae. And in the case of the iris vessels, as Dr. Robert Lambert has shown, in man they possess no muscle but are simply smooth fibrocollagenous structures without cells, much like aged arterioles in the spleen. But in the dog, the iris vessels are thick, and the thickness is due to the presence of considerable smooth muscle. Differences in species are not new to us, and we are all well aware of the need to beware in transferring the results of animal experiments to man.

Dr. Smith closed his discussion with a question, and I have a similar question that is disturbing me. Why is it that the necrotizing lesions are virtually confined to the arterial side of the circulation? I have not found

them in the portal vein or the pulmonary vessels, or in the bladder or uterus I have found them in the vessels of the bladder but not in the muscles of the bladder alone

Finally, I am sure that Dr Winternitz does not equate the necrotizing factors that are obtained from autolysis of the kidney with the mechanisms that are operating in an ischemic kidney that is not necrotic. In much of the renal material I have examined I have been unable to find any evidence of necrobiosis, in others, considerable necrosis. So, I am reasonably certain that some differences in the lesions may be attributable to the presence or absence of infarcts, and they should be differentiated from those experiments that are based on organ extracts only.

DR BENJAMIN JABLONS (*by invitation*)
As one who has been a protagonist of kidney extract therapy for a period extending over almost ten years, I am afraid I would feel as though I had been indicted after having listened to Dr Winternitz's masterly contribution on the necrotizing and thrombotic effect of substances extracted from the kidney on various parts of the cardiovascular tree if it were not for one important point that needs to be emphasized—and that is that we must differentiate between various types of kidney extracts. In other words, a kidney extract made with saline solution from the kidney tissue left after preliminary acetone-ether treatment and subjected to the various procedures outlined by Dr Winternitz is not the same as one made from substances extracted from the kidney by acid alcohol and water. Biochemists tell us that when one changes the acid reaction—i.e., the pH of a solution that is used as a solvent with kidney tissue—one obtains materials that differ chemically and pharmacologically and produce different effects. One point that we have emphasized from the earliest days of our experiments is that kidney extracts must be made with tissue that is frozen in the slaughter house. The material must be taken out of the carcass within twenty minutes of the death of the animal and frozen immediately with dry ice. We have found that even refrigerating this material in the frigidaire for three hours previous to extraction is insufficient to prevent the production of considerable quantities of choline, histamine, and other biogenic amine substances that Dr Smith referred to. We also found in our early experiments that when we used material which contained slight traces of protein we would get these local necrotizing effects

when it was injected into animals, and we also found this marked increase in the coagulability reported tonight, so that from the time of the earliest days of our work we were careful to make a protein-free extract because it does not produce these local lesions when injected into animals or human beings. I think that, for the sake of clarity and to avoid confusing the various fractions that are now receiving so much attention on the part of many workers in different laboratories, the extracts should be named either by the method used to extract them or in some other identifying manner, so that when we speak of an acid alcohol extract we refer to a substance that belongs in one category and, when we speak of the kidney extract prepared by Dr Winternitz, we are dealing with a protein residue freed of certain soluble substances by acetone-ether, fractionated by the various procedures that he spoke of. Then we know that we are speaking of something entirely different.

Again, I want to express to Dr Winternitz my thanks for the facts that he has brought to us, his paper will help to clear up many things that have puzzled us for a long period of time.

DR M C WINTERNITZ. May I first thank the discussers for their kindness? Dr Smith has brought forward a significant approach. With others, we also realize that disturbances in deamidization may be associated with some of the disease phenomena that follow ischemia of the kidney. Our point of view differs somewhat from that expressed by Dr Smith. We do not believe that the amines indicated are causatively involved in the production of the lesions. These amines would be removed in the preparation of the extracts we have used. We are of the opinion that disturbances in the enzymatic deamidization may lead to muscle cell necrosis, but the evidence is not adequate to support this hypothesis at present.

The extracts we have employed were preparations of normal kidney. Necrotic kidney was only used in preliminary experiments. As Dr Jablons has so clearly indicated, it is necessary to remove the organs promptly on the death of the animal, freeze them at once, and avoid any possible autolysis in their preparation. These specifications have been followed minutely, and the extracts have been kept at -18°C in small, individual containers until they were used.

The differences manifested after narrowing the ureters as distinct from the arteries have interested us. With the latter, as is well known, hypertension is usually marked. It

is infrequent with the former, and this raises the question of the mechanisms involved in the two procedures. Ureteral narrowing results, first, in compression of the vein and interference of the escape of products that follow the passive congestion of the organ. But the compression of the vein is not at a constant level, and many possibilities for disturbed chemical change may be involved.

Dr Smith referred to Dr Schroeder's recent publication. In this association it may be pertinent to mention that Dr Philip Cohen has carried out a few preliminary experiments for us to determine whether kidney extracts inhibit special enzymatic functions of smooth muscle. Should this approach prove feasible, it might be of considerable aid in clarifying some of the enzymatic mechanisms associated

with muscle necrosis. It should also be mentioned that while muscle necrosis is rare with other organ extracts it does occur with that of the testicle, particularly in the nephrectomized animal. This happens in the absence of hypertension and is of importance to the morphologist who frequently encounters arteriosclerosis without either hypertension or renal disease. It should be said in reply to Dr Smith's question that the walls of the pulmonary vessels show necrosis in the experiments with tissue extracts.

As Dr Jablons has indicated, the extracts he has utilized are quite different from those employed by us, and it is essential to state clearly just how an extract is prepared and the nature of the fraction that is used in any particular study.

VACANCIES IN THE U S NAVAL RESERVE MEDICAL CORPS

A number of vacancies have been created in the Medical Reserve Corps of the United States Navy. These include the rank of Lieutenant, Junior Grade and Lieutenant, also a number of appointments as Lieutenant Commander for Special Service (surgeons, orthopedists, otolaryngologists, neurologists, urologists, intern-

ists, neuro-psychiatrists, radiologists, and pathologists).

Further information is obtainable on communicating with the District Medical Officer, Headquarters, Third Naval District, 90 Church Street, New York City. The telephone number is REctor 2-9100.

EXAMINATIONS FOR MEDICAL POSITIONS ANNOUNCED BY CIVIL SERVICE COMMISSION

Examinations for three types of medical positions in the government service have just been announced by the Civil Service Commission. This is another indication of the great demand for technically trained personnel of every kind in the defense program. Each of these positions has been open to competition within the past year, but the demand grows even faster than the supply.

Junior medical officer positions at \$2,000 a year will be filled at St Elizabeth's Hospital in Washington, D C. There are two types of internship: Rotating and Psychiatric Resident. The rotating internship consists of 4 months of surgery, acute medical service, and of chronic medical service, 2 months of obstetrics and of pediatrics, on affiliation, 3 months of general laboratory work, and 6 months of psychiatry. To qualify, applicants must be fourth-year students in a Class A medical school. Applicants must show completion of the course prior to June 30, 1942, before they may enter on duty.

Graduates in medicine who have already served an accredited rotating internship are offered a postgraduate internship of 1 year of psychiatry (American Medical Association Classification 2, Type B). To qualify for this type of appointment, applicants must have completed their fourth year of study in a Class A medical school subsequent to December, 1935, and must have

either a B M or M D degree. Applications will be accepted at the Commission's Washington office until November 15, 1941, and will be rated as soon as practicable after receipt.

Medical technical assistant positions at \$2,000 a year and medical guard-attendant positions at \$1,620 a year will be filled in the Mental Hygiene Division of the U S Public Health Service. Applicants must be registered graduate nurses, or have been honorably discharged (within the 10 years immediately preceding date of receipt of application) from active service in the Medical Corps of the Army or Navy, or have had 3 years' service as guard-attendant in a federal penal or correctional institution. In addition, for the technical assistant, applicants must show that their experience has included one year of responsible training or experience in Clinical Laboratory Technique, Pharmacy, or X-ray Laboratory Technique. Applications will be accepted until further notice. Persons who were rated eligible for these two positions in the examination which closed in February of this year need not apply for this new examination as eligibles from both examinations will be combined on the new register.

Further information and application forms may be obtained at any first- or second-class post office or from the Civil Service Commission in Washington. Qualified persons are urged to file their applications at once.

Medical News

County News

Greene County

Nomination of officers, in preparation for the October election, was made at the midsummer meeting of the county society at Pines Inn, Windham, on July 8. The following were nominated:

Dr William Vernon Wax, president, Dr Elisha B Van Deusen, vice-president, Dr William M Rapp, secretary, Dr Mahlon H Atkinson, treasurer, Dr Percy Waller, chairman of legislative committee, Dr T Earl McQuade, chairman of public relations, Dr Kenneth F Bott, delegate to State Society, Dr William A Petry, alternate delegate.

Dr Herbert F Weinauer presided. Dr Carl Eggers, New York City surgeon, spoke on "Cancer of the Digestive Organs."

Kings County

Officers of the Medical Society of the County of Kings and the Academy of Medicine of Brooklyn, Pediatric Section for the coming year are as follows: president, Dr Sydney Nussbaum, Brooklyn, secretary, Dr Harry S Bikoff, Brooklyn. Place of meeting is 1313 Bedford Avenue, Brooklyn, and the time 9 00 P M., on the fourth Monday of each month, October to April, inclusive.

Madison County

Twenty-seven members of the county society played golf in the afternoon at the Oneida Country Club on July 10 and listened to a program on scientific topics in the evening at the clubhouse. Dr Howard Beach, of Oneida, is president and Dr L S Preston, of Oneida, is secretary.

Golf tournament winners: low gross, Dr J D George, Jr, of Verona, low net, Dr Ernest Freshman, of Oneida, blind scores, Dr John Sill, of Hamilton, and Dr Ellsworth, of Madison. The tournament lasted most of the afternoon. Dinner was served at 6 30 P M.

Three Syracuse doctors, who provided the program, follow:

"Recent Advances in Neuropsychiatry," Dr Eugene N Boudreau, "Medical Aspects of Hypertension," Dr J G Fred Huss, "Surgical Aspects of Hypertension," Dr Frederick S Wetherell.

Montgomery County

Dr Elmer Harrison Ormsby, of Amsterdam, who died on July 17, had a distinguished medical military record in the first World War. "His professional relations," says the Amsterdam Recorder, "were with the Amsterdam City Medical Society, of which he was a past president, the Medical Society of the County of Montgomery, in which he held practically all the offices at various times, the New York State Medical Society, the American Medical Association, the Alumni Association of the Albany Medical College, the Surgeons Club of Rochester, Minn., of which he had been president, and the New York State Association of School Medical inspectors which he served as secretary-treas-

urer. At the time of his death he was president of the Fourth District Branch of the New York State Medical Society and was engaged in preparing a program for the annual meeting of the branch. He was also a member of the House of Delegates of the state society."

Nassau County

Doctors of South Nassau Communities Hospital hold the golf championship of the Nassau County Medical Society, having won the first leg on a new trophy after a tournament held as part of the annual society outing at Lido Country Club on July 9.

The team defeated doctors representing Nassau Hospital, which was second, and North Country Community Hospital, which was third. Dr R M Bowles, of Hempstead, was captain of the winning team. The trophy must be won three times for permanent possession.

About 100 attended the outing. Dr Martin L Sowers, of Far Rockaway, with 79, won low gross, Dr John M Galbraith, of Glen Cove, the low net, 71. Dr Joseph Tibone, of Rockville Centre, Dr A M Bell, of Sea Cliff, and Dr William Burke, of Hicksville, placed in that order in the kicker's handicap.

Dr Aaron L Higgins, of Rockville Centre, retiring president of the society, handed over the gavel to Dr Charles W Martin, of Woodmere, at the dinner in the evening.

Oneida County

The county society held its outing on July 8 at the Utica Gas and Electric Club House at Trenton Falls. The speaker was Dr Samuel J Kopetzky, president of the State Society.

Richmond County

The county society approved the Medical Expense Fund of New York, Inc., at a special meeting on July 23.

St Lawrence County

The county society held its second social meeting of the year at Massena Country Club on July 24. There was a meeting at noon. Luncheon was followed by golf and cards. The wives of the members were invited.

Suffolk County

The Hampton Clinical Society met on July 25 with the following program: "Urological Subject," Dr William Gaynor, "Deep Infections of the Neck," Dr deGraff Woodman, of New York, "Movies Plastic Surgery" (Davis & Geck).

Washington County

The summer meeting of the county society was a social evening, without scientific program, held at the Hotel Willard, Cleverdale, on Lake George, on July 8.

About fifty of the doctors and their wives were present. Some of the members came early and enjoyed the lake in the afternoon. After

dinner, the latent talent of the group was exemplified in group singing with Mrs L. A. White at the piano—Reported by D. M. Vickers, M.D., Secretary

Westchester County

An urgent appeal to doctors to act as first-aid instructors in every community in the county has gone out from the headquarters of the Westchester defense council. In connection with plans for civilian defense, the council is planning to give courses in first aid at conveniently located points in every town and village.

Cooperating with the county defense council in its efforts to enlist doctors as first-aid instructors are the Medical Society of the County of Westchester and the Westchester chapter of the American Red Cross.

A letter from James E. Bryan, executive secretary of the medical society, to county doctors says: "A survey of police throughout the

county shows only 10 per cent of them have had any first-aid training. It is an essential part of the national defense program to train all the uniformed public authorities and a large number of lay defense workers in each community in the fundamentals of first aid."

Each doctor would teach in his own community, according to the plan, and courses would be arranged to suit the convenience of the instructor as far as possible.

Yates County

The Lake Keuka Medical and Surgical Association, in its forty-second annual session, elected Dr. Walter A. Callahan, of Rochester, as president to succeed Dr. Leon M. Kysor, of Hornell. Dr. Kenneth G. Rowe, of Dansville, was elected vice-president and Dr. Virgil H. F. Boeck, of Dundee, was renamed secretary-treasurer. The association includes medical men from twenty-two counties in New York State and several in northern Pennsylvania.

HEALTH HERE AND IN EUROPE

In the midst of Attorney-General Arnold's cudgeling and sniping at the medical profession and the spreading contagion of the American Association for Social Security's support of the spoils system in the practice of medicine by the government, it is refreshing to consider the health record in this country for the year just ended, remarks the *Connecticut State Medical Journal*. True, 1940 did not set a new low mark in mortality figures, but it does rank with the best health years on record. The Metropolitan Life Insurance Company has found that among its many millions of industrial policyholders living in the United States and Canada the death rate for 1940 was 7.60 per 1,000, the equal of the lowest figure ever registered for this group. The decline in mortality rate among policyholders of this large company has been 40 per cent between 1911 and 1940, and this has resulted in a great saving of lives at virtually every period of life.

Ten diseases and conditions recorded lower mortality rates in 1940 than in any previous year—namely, measles, scarlet fever, whooping cough, diphtheria, pneumonia, tuberculosis, diarrhea and enteritis, appendicitis, puerperal diseases, and homicide. Influenza and suicide showed an improved mortality rate. Increases in mortality were recorded from diabetes, cancer and the cardiovascular renal diseases, an indication of the increased proportion of policyholders at the older ages.

We turn to Europe, torn with strife and starving because of a few insanely selfish political leaders. Europe has experienced its worst record in many years. Cerebrospinal meningitis in England during 1940 claimed about 12,500 lives, eight times the mortality for 1939. An influenza epidemic in the first quarter of the year, aided and abetted by war conditions, accounted for 5 per cent of the deaths and was two-thirds above that for the preceding year. Infant mortality for the first quarter rose from 65 to 77 per 1,000 live births. Civilians numbering 23,081 were killed in air bombardments in England during 1940, and fatal accidents during the first fifteen months of the year rose to 11,424.

Data on mortality from the Continent is fragmentary. Cerebrospinal meningitis was on the increase. Deaths from typhus rose appreciably, particularly in Rumania. It is to be feared that the frightful breakdown in sanitary conditions that occurred in and after the last war cannot be avoided in this war. Typhoid and dysentery were abnormally high in frequency in certain countries. The outlook for 1941 is extremely uncertain. Crowding in air shelters with poor sanitary conditions in many of them may be the means of spreading communicable and infectious diseases to pandemic proportions. Civilian medical service is already suffering from the inroads of war service requirements. Apprehension is felt everywhere for the health of Europe.

Hospital News

Newsy Notes

The Arnot-Ogden and St Joseph's hospitals in Elmira could increase their capacities more than 50 per cent in case of war emergency, they show in a survey prepared in line with disaster plans of the Hospital Association of the State of New York and the American Hospital Association. "Triple Cities" hospitals in Binghamton, Endicott, and Johnson City are prepared to hospitalize a total of 1,743 patients in event of sabotage or war emergency. This represents an increase of 679 cases over the normal patient load.

Beware of "bootleg" hospitalization insurance sold through the mail by companies not qualified to do business in this state, is the special warning of the Buffalo Better Business Bureau issued to Buffalo families.

"In many cases we have found that these concerns use extremely misleading advertising and certificates," said Gordon E. Smith, bureau manager. "In other instances there may be hidden clauses which change the meaning of the policy or increase its cost to the policyholder."

Foreseeing a Federal drain on the staffs of New York City hospitals, Mayor LaGuardia is backing a bill in the City Council permitting the employment of alien physicians, nurses, and interns who have declared their intention of becoming citizens.

Introduced by Councilman Anthony J. Digiovanna, Brooklyn Democrat, the bill would permit such employment up to July 1, 1942. Under the Lyons Residence Law the appointment of aliens to city posts is now forbidden.

A referee's report alleging that Doctors Hospital in New York City has engaged in "so-called charity" rather than in real charity, recommends that the institution be compelled to pay back taxes and interest of \$500,000.

The Boro Park General Hospital in Brooklyn

has changed its name to Brooklyn Doctors Hospital.

At a meeting of the Hospital Council of Albany on June 27, St. Peter's, Brady Maternity, Memorial and Albany hospitals announced increased room rates of approximately 50 cents a day to all private and semiprivate patients. A revision upwards of certain laboratory and other charges also was announced.

The Israel Zion Hospital of Brooklyn is opening a Residency in Pathology (approved by the Council on Medical Education and Hospitals of the A.M.A.) to physicians who have had a one-year general internship in an approved hospital. For further information applicant may write to the Superintendent.

Improvements

The town board of Sidney has voted to proceed alone to erect a hospital, after the town boards of Unadilla, Masonville, Bambridge, and Guilford failed to unite in a five-town project.

The Stevens Hospital at Granville plans to install 25 beds in the former Sheldon property and convert it into a hospital at a cost of \$40,000.

The Board of Commissioners of the Oneida City Hospital plan to build a 25-room addition if government aid can be secured.

Huntington Hospital contemplates a new wing

The American Legion Auxiliary's Salon 154, Eight and Forty, has given an iron lung to the Syracuse City Hospital.

The Flushing Hospital will soon install its much needed auxiliary battery lighting system for emergency use, the gift of the Douglaston Branch of the Women's Auxiliary of the Hospital.

TUBERCULOSIS AND MEDICAL PREPAREDNESS

"So far as tuberculosis is concerned, the cost in the last war has been at least \$959,000,000 just for vocational training, insurance, compensation, and hospital care. This figure does not include the cost of hospital construction. Today money is being spent at the rate of \$3,000,000 a month on tuberculous soldiers. Flatly, it costs around \$10,000 to induct a man suffering from tuberculosis and \$50 a month for the rest of his life, plus compensation benefits for his depend-

ents after his death. When you compare the above figures with the slight cost of making x-rays of the chests of all draftees it is only reasonable to believe that a considerable saving can be effected by the use of the x-ray. In addition to all this, we haven't counted the damage that the tuberculous soldier does in his contact with the other soldiers"—Donald B. Cragin, M.D., president, Association of Life Insurance Medical Directors.

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Workmen's Compensation—Alleged Fraud in Physician's Report

THE statement that cases involving the rendering of medical care to an injured workman under the terms of a Workmen's Compensation Law sometimes lead to litigation of all sorts is borne out by a case recently decided by the highest court of one of the Southwestern States.*

The plaintiff, A, was in the employ of a county on a construction job. While at work he received an injury when some cinders fell upon him. He reported the accident to the State Industrial Commission, and it was determined that he was entitled to compensation payments, which he received for about nine months at the rate of \$90 per month. At the end of that time the Commission, in order to determine whether payments should be stopped, sent him to three physicians for the purpose of undergoing a physical examination. These doctors, who were regularly employed by the Commission, after examination reported that A was cured of the injuries that he had received in the accident and that the resulting ill effects had disappeared. Payments of compensation were thereupon terminated.

An action was brought by A, the injured workman, against the physicians who had examined him to recover the sum of \$100,000 as claimed actual damages and \$50,000 as claimed punitive damages. The charge in the complaint was that the defendant physicians had defrauded plaintiff of payment of compensation and that they had conspired with the Industrial Commission to prevent plaintiff from obtaining compensation to which he was justly entitled by means of a false report concerning plaintiff's physical condition and the causes of that condition. It was claimed that both the Commission and the doctors knew the report to be false.

The case was tried before a jury. Upon the trial, in his attempt to show that, at the time of the physical examination complained of, he was properly entitled to compensation, plaintiff gave certain testimony himself as to subjective symptoms and their effects. He called but one physician, and this physician merely asserted that some x-rays of plaintiff showed certain abnormalities but made no attempt to express an opinion that the abnormalities were due to the injury that plaintiff had sustained during the course of his employment. Plaintiff also called four lay witnesses, whose testimony, in substance, was that plaintiff had complained to them of his physical condition and his inability to work.

There was no testimony showing that the Commission had requested or desired a false report from the physicians or that the Commission had ever known their report to be false.

The Trial Court submitted the case to the jury, and a verdict of \$6,000 was returned in favor of plaintiff, divided as \$2,000 for actual and \$4,000 for punitive damages.

The defendants appealed from the judgment and, upon appeal, the Supreme Court reversed and directed judgment for defendants. In so ruling the Court said in the course of the opinion:

"The material allegations must be proved by a legal sufficiency of evidence. The gist of the action upon this theory is fraudulent representations by defendants to the Commission. Such representations may either constitute actual fraud, when the representations are, to the knowledge of the party making them, false, or else constructive fraud, when the party does not know their falsity, but makes them recklessly, when it is his duty to ascertain the truth before speaking. We consider the evidence from each standpoint.

"It must be remembered that the alleged false statements on which the action is based are not positive statements of fact. Therefore, in the opinion of defendants as medical experts, there was no compensable condition of plaintiff on May 9, 1938, as a result of the accident of the previous August 3. It is a well-known fact that medicine is not an exact science like mathematics, physics, or chemistry, but is peculiarly, and above all others known to man, an uncertain one, based on the opinion and best judgment of men who have made a life-long study thereof. Particularly is this true when the question arises as to the specific cause of a physical condition claimed to exist. In the present case, in order to establish actual fraud, it was necessary for plaintiff to show by clear and convincing evidence that the accident of August 3 was the cause of an existing physical condition on May 9, which entitled him to compensation under the law, and that the defendants knew this to be true."

"It is admitted there is no direct evidence that defendants knowingly made a false statement as to plaintiff's condition or the cause thereof, but much time was spent in arguing as to the evidential effect of the fact that defendants received compensation from the Commission for their services in making the examination of plaintiff. If this be proof of actual fraud, then every doctor and every lawyer who expresses an opinion, concerning the correctness of which a doubt may later arise, and receives a fee therefor, may be found guilty of fraud on that evidence alone. Plaintiff's counsel admit there is no evidence that the Commission wanted a false report, and, indeed, insisted that they did not, but desired only the truth. What conceivable motive, under such circumstances, was there for defendants to make a false report to the Commission?

"Fraud is never presumed nor can it be found to exist on a mere suspicion as to the possibilities thereof. It must be established

* *Rice vs. Tinsau* 112 Pac. (2d) 886

by clear and convincing evidence and plaintiff has completely and utterly failed to present evidence which would even raise a reasonable suspicion of actual fraud "

The Court also said

"We come next to the question of constructive fraud. Even though defendants had deliberately, knowingly, and intentionally made a false report, we think that if they failed to use proper care in making their investigation as to plaintiff's condition, it would have been constructive fraud. But the test of proper care in a case like this is the same as in an action for malpractice. It is whether the physician possessed and exercised the same care in the performing of his duties as was ordinarily possessed and exercised by other physicians of the same class in the community in which he practiced. Since the test is in regard to the knowledge and conduct of other physicians, it is

practically universally held that only physicians are competent witnesses as to what that standard of knowledge and conduct is. There is not even a suggestion in the record that each and all of the defendants did not possess and exercise not only the ordinary but the highest degree of skill in their profession in their examination of plaintiff. There is no evidence whatever that there was any constructive fraud.

"Since plaintiff's counsel admit there was no evidence of a conspiracy between the Commission and defendants to have a false report made, and since the evidence utterly fails to raise even a reasonable suspicion that defendants were guilty of either actual or constructive fraud in their report to the Commission, which admittedly desired only to do that which the law required, the judgment cannot be sustained."

Inquiries

YOUR counsel received the following inquiry from the Superintendent of a hospital

"Dear Mr Brosnan

"Could you advise us if there is a form to be signed at the admission of a patient whereby he or she would waive claims for any accidents that may occur while an inmate in an Institution. Also a similar form relative to waiving liability should injuries occur to visitors of patients

Very truly yours,"

Your counsel's reply was as follows

"Dear Sir

"Generally speaking an institution cannot legally in advance of an accident secure a release from the injured party. This would apply to patients and visitors. Perhaps some institutions do have the patient or visitor stipulate that the institution shall be relieved of the responsibility of any injuries received by the patient or visitor irrespective of negligence on the part of the institution or its employees, but, if so, it is generally on the theory that such releases might act as a deterrent against suit being brought since the injured party might feel that this release will deprive him of any cause of action and would not go to the trouble of consulting a lawyer

"Hospitals, of course, have forms which are perfectly legal, i.e., forms the patient signs consenting to operation and other forms by which patients release the hospital from responsibility if they leave contrary to doctors' orders and by so doing assume the risk of any injury that they may sustain as a result of the failure to follow the orders of the doctors or hospital authorities

"I trust that this answers the inquiry contained in your letter

Very truly yours,"

Your counsel received the following inquiry

"Dear Mr Brosnan

"I have an assistant coming in my office September 1. He is a graduate of University of , and just completed two years internship in this state. In June he took his state boards here and just found out he failed in one subject

"I would like to know if he can work in my office and make house calls, pending his receiving his license to practice.

Yours very truly,"

Your counsel's reply was as follows

"Dear Doctor

"I note that you inquire as to whether a medical school graduate who has completed two years internship and who has taken his state boards but failed in one subject may properly work in your office and make house calls pending his being licensed to practice

"I believe that it would be extremely dangerous for you to permit this young man to do the work referred to since there can be no question that under the definition of the practice of medicine as set forth in the Education Law he would be engaging in the practice of medicine without a license and would be subject to prosecution for so engaging in practice.

"While the Education Law makes specific provisions whereby one who has not yet obtained his license may serve an internship in a hospital and there actually do the work of a licensed physician, there is no provision in the law permitting an unlicensed physician to engage in the practice of medicine as an assistant to a licensed physician in private practice

"I strongly advise against the proposed arrangement, since not only the young man may encounter difficulties but the situation might lead to disciplinary proceedings being brought against you upon charges of aiding and abetting an unlicensed practitioner

Very truly yours,"

A physician is an unfortunate gentleman, who is every day called upon to perform a

miracle, namely, to reconcile intemperance with health.

Public Health News

Sulfathiazole to Be Distributed by the New York State Department of Health for the Treatment of Gonococccic Infections*

ON OR about August 1, 1941, the New York State Department of Health will distribute sulfathiazole for the use of registered doctors of medicine, and hospitals and clinics, for the treatment of gonococccic infections. *The drug will be available for the treatment of all patients irrespective of their financial status.* Packages of forty tablets (0.5 Gm. each) may be obtained upon request from regular laboratory supply stations which are now distributing sulfathiazole and sulfapyridine for the treatment of pneumococccic infections.

As in the case of sulfonamides distributed for the treatment of pneumococccic infections, sulfathiazole will be dispensed in bottles bearing the manufacturer's label in a form that may be detached, leaving on the package as it finally reaches the patient a label upon which the physician has written his instructions. The label will, however, carry an identifying number that will not be intelligible to the patient. It is recommended that the manufacturer's label bearing the name of the drug be detached in order to discourage the possibility of self-medication should any of the drug be left after treatment of a case for which it was prescribed.

How to Obtain the Drug

The request slip now used for sulfathiazole and sulfapyridine has been revised for use as well in requisitioning sulfathiazole for the treatment of gonococccic infections. In requesting the drug for gonorrhea cases, it is necessary only to check the slip accordingly. The name and address of the patient and bacteriologic findings may be omitted.

The above instructions apply only to requests for sulfathiazole for the treatment of gonorrhea. Additional data including the name and address of the patient, date of onset, bacteriologic findings, and place of examination, if done, must be supplied when requesting sulfonamide drugs for pneumococccic infections.

Since prescriptions are required in the dispensing of sulfonamides, requests for these compounds for any purpose must be signed by the physician.

Warning

In obtaining the sulfonamide drugs it is essential that physicians specify the infection for which the drug is desired, since individual packages for gonococccic infections differ in size from those dispensed for use in pneumococccic infections.

* Announcement received July 17 from the Director of the Division of Syphilis Control, New York State Department of Health.

THE PLACEBO

The placebo has no place in medicine unless it be given in answer to the cry of an anxious family that some medication be given. Prescribed solely to satisfy a patient, such treatment is a therapeutic lie and lays a foundation for mistrust or disillusionment, and is a poor substitute for re-education. More than thirty years ago, Dr. Richard Cabot cited an illustrative case to a group of us who were students at the Massachusetts General Hospital. A neurotic young woman came to the dispensary claiming that she had a frog in her stomach. The diagnostic study showed nothing physically wrong. Perhaps pressed for time, lazy, or possibly mistrustful of his therapeutic ability, the physician on duty prescribed methylene blue,

indicating that the medicine would dissolve the amphibian. He told the lady proof of the successful action of the drug would be visible to her—she would void green urine. She did and was convinced! But the therapeutic triumph had only a brief day. Within a short time the patient returned more distressed than ever.

"Doctor, my first frog was a female—she laid eggs before she was dissolved, and now the tadpoles make me feel worse than their mother did!" Nor could she be convinced that her first gastric tenant was a male!—Austrian, Charles R., M.D. *New England J. Med.* 223:699 (October 31) 1940, quoted in *North Carolina Medical Journal*.

Books for review should be sent to the Book Review Department at 1313 Bedford Avenue, Brooklyn N Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and interest to our readers.

REVIEWED

Biological Aspects of Infectious Disease By F M Burnet, M D Octavo of 310 pages, illustrated New York, The Macmillan Company, 1940 Cloth.

In this book the author presents a general survey of infectious disease and of the agents that cause it, as well as the defenses that the body has developed to combat it. His approach to the problem is from the broad point of view of the biologist trained to see the "ecologic" problems involved and, in particular, the importance of consideration of the nature and activities of pathogenic microorganisms as they fit into the scheme of living things.

The tremendous research activity that has followed Pasteur's revolutionary discovery of the germ theory of infectious diseases has been naturally directed to the solution of the etiology and specific prevention and therapy of these morbid entities. Until recently, the possibilities of a more broad biologic approach have been less explored. Yet none will be apt to question the value of the point of view that sees infectious disease as a product of the struggle between man and microorganism of the "same order as many other types of competition between species in nature" and, thus, a "manifestation of the interaction of living things." Like every other living organism, pathogenic bacteria thrive at the expense of other forms of life. In the search for food on which to multiply, every nook and corner of the earth that can be exploited for a livelihood is filled. The host-parasitic relationships thus established have far-reaching importance and significance, and the laws that govern them are yet most incompletely understood. While it appears evident that a balance or equilibrium has been developed over centuries, concerning this we have little information as yet.

The book, therefore, is a stimulating treatise and one that should appeal to a wide variety of readers.

JOSEPH C REGAN

Textbook of Medicine By Various Authors Edited by J J Conybeare, D M Oxon Fifth edition Octavo of 1,131 pages, illustrated Baltimore, Williams & Wilkins Company, 1940 Cloth, \$7.50

This edition follows the plan of previous ones. It covers a large field including venereal diseases, diseases of infants, psychologic medicine, and common diseases of the skin. There is also a brief appendix on "Examination for Life Assurance."

An article on "Congenital Cystic Disease of the Lung" has been added, also one on "Hermiation of the Nucleus Polypus," and the section on "Diseases of the Alimentary Tract" has been considerably revised.

As now seems necessary, many authors have contributed to this book which is recognized as one of the standard works.

W E McCOLLOM

Manual of Physical Diagnosis with Special Consideration of the Heart and Lungs. By Maurice Lewison, M D, and Ellis B Freulich, M D Octavo of 317 pages, illustrated Chicago, The Year Book Publishers, Inc 1941 Cloth, \$3.00

This new manual of physical diagnosis is a highly satisfactory introduction to this important art. It is concise, complete, and well written, and its extremely reasonable price will commend it to medical students. Nothing important is omitted which may be found in larger volumes covering the same material. A special word of praise should be given to the authors for avoiding the temptation to add extraneous material properly belonging in works on laboratory diagnosis. This often clutters up manuals of physical diagnosis adding unnecessarily to cost and bulk. There are 75 illustrations, all with the exception of Fig 59 are well chosen and well printed.

MILTON PLOTZ

The Periodicity and Cause of Cancer, Leukaemia and Allied Tumors. With Chapters on Their Treatment By J H Douglas Webster, M D Octavo of 178 pages Baltimore, Williams & Wilkins Company, 1940 Cloth, \$3.50.

Contrary to the popular opinion that the usual course of neoplastic tumors is a steady progressive one, the author offers evidence of alternations of active and quiescent phases in tumors that assume a periodicity—a time pattern. He believes this to be a fundamental and intrinsic characteristic of neoplastic tissue which is evident in both primary and recurrent tumors.

A statistical analysis of 820 cases shows this characteristic in 96 per cent. Clinical examples are presented in a clear outline form.

The second part of the book discusses the theories of cancer and the physical, biologic, and pathologic basis of periodicity. The author offers this as proof of the virus theory for cancer.

HARRY MANDELBAUM

Plague On Us By Geddes Smith Octavo of 365 pages, illustrated New York, The Commonwealth Fund, 1941 Cloth, \$3.00

This is a text for the layman in which some facts and theories about communicable disease are presented and discussed in an interesting manner.

Clinical diseases are presented with a short historical summary and brought up to date in such a way as to stress their exact nature. Throughout the book the importance and the role of causative organisms, the host, and the environment are stressed, and the necessity for minute investigation and research for the final solution of some of the problems involved is emphasized.

The text is written in good style, it is easy reading, and its 350 pages will be found extremely interesting.

E R. MARZULLO

Bone Graft Surgery in Disease, Injury, and Deformity By Fred H. Albee, M.D. Octavo of 403 pages, illustrated. New York, D Appleton-Century Company, 1940 Cloth, \$7 50

In this book the wide scope of bone graft surgery is presented by a pioneer in this field. The principles of bone grafting and its application to disease, trauma, and deformity is fully covered. The text is amply and adequately supplemented with roentgenograms of the various autogenous bone grafting procedures and with numerous excellent diagrams illustrating the author's ingenious methods of preparing and applying the various types of bone grafts to pathologic conditions. Throughout the text the author's operative technic for the bone grafting operations is clearly described. His arguments in favor of the use of the bone graft in its many indications and of the superiority of the tibial graft are clearly and convincingly presented. Although one might take exception to the use of the bone graft as a means of expediting rehabilitation in fresh fractures of the spine, the opinions in general expressed by the author throughout the book are sound and have stood the test of time. The book is divided into nine chapters, covering comprehensively the general principles of bone grafting, armamentarium of the orthopedic surgeon, spine fusion, bone graft surgery of the hip joint, bone graft surgery of ununited fractures, bone graft surgery for replacement of bone, plastic bone graft surgery, arthrodesing bone graft operations, and bone block operations. The chapters on the general principles of bone grafting and bone graft surgery of ununited fractures are exceptionally interesting and illuminating. It is a complete treatise on the bone grafting phase of orthopedic surgery and is written by a surgeon who has not only pioneered in this type of work but has developed it to its present stage of perfection through years of experience. The book is a tribute to the author and is an indispensable addition to the library of the orthopedist.

L. GASTON PAPAE

Roentgen Interpretation By George W. Holmes, M.D., and Howard E. Ruggles, M.D. Sixth edition. Octavo of 364 pages, illustrated. Philadelphia, Lea & Febiger, 1941 Cloth, \$5 00

This is the sixth edition of a text book on x-ray diagnosis. The great demand for the previous editions indicates the popularity of this work over a period of years, and this, the latest edition, offers all of the past contents and many new features. Dr. George W. Holmes, one of our most outstanding American radiologists, has kept the book up to date since the untimely death of its co-author, Dr. Howard E. Ruggles.

The subject matter is comprehensive, and all branches of the specialty are included. To compensate for thoroughness of detail, which can scarcely be anticipated in a book of 355 pages, there is an excellent bibliography at the end of each chapter to which the student may refer for further information.

The general plan of presentation remains the same as heretofore, and the eleven chapters of the first edition still appear, chapters having been altered as additional knowledge has come to light.

Medical diagnosis of today is considerably handicapped without modern x-ray studies, so that any student or practitioner who would acquaint himself with the general value of roentgenology would do well to digest thoroughly the subject matter of this book.

MILTON G. WASCH

Spermatozoa and Sterility A Clinical Manual. By Abner I. Weisman, M.D. Octavo of 314 pages, illustrated. New York, Paul B. Hoeber, Inc., 1941 Cloth, \$5 50

Dr. Dickinson in the foreword to this volume epitomizes the *raison d'être* for a text such as this when he states "No change in the medical-social field has been more rapid than the recent allotment of a large share in sterile mating to the male partner." The author throughout the text has evaluated the role of the male in the barren marriage.

Dr. Weisman clearly discusses and evaluates the various constituents of the seminal fluid, its physical and chemical properties, the methods of analysis, and the interpretation of the morphology of the sperm population.

The text is easily read, precise, and well illustrated. Although intended primarily for the general practitioner, some of the author's techniques in spermatozoa study, particularly that of the aspiration method for the recovery of spermatozoa from within the uterus or fallopian tubes and artificial insemination, can hardly be recommended as procedures for the "family physician."

The discussion of the female factor in the problem of sterility is concise, clear, and ample for a volume such as this is intended.

There seems, however, to be a paucity of the author's clinical experience and results with the various endocrine products as well as with artificial insemination. The bibliography of the relevant literature is up to date and unusually complete. The book is well recommended to all who are interested in the problem of human reproduction.

SAMUEL L. SIEGLER

Lipidoses Diseases of the Cellular Lipid Metabolism. By Siegfried J. Thannhauser, M.D. Edited by Henry A. Christian, M.D. Octavo of 370 pages, illustrated. New York, Oxford University Press, 1940 Cloth, \$6 00

Here is a sound authoritative volume on that complicated group of diseases involving cellular lipid metabolism. The author has the happy faculty of clear expression and exposition, and his material is arranged in an orderly fashion. He has done much original work on the chemistry of the lipids which is included in the first chapter. Schuller-Christian's disease, Gaucher's disease, and the Niemann-Pick's syndrome are well described and brought up to date in relation to the newer knowledge in cellular lipid metabolism. The reviewer does not hesitate to recommend this volume not only for its general interest to internists but also because of its great value as a book of reference.

EDWIN P. MAYNARD, JR.

Criminal Youth and the Borstal System. By William Healy, M.D., and Benedict S. Alper. Octavo of 251 pages. New York, The Commonwealth Fund, 1941 Cloth, \$1 50

Books

Books for review should be sent to the Book Review Department at 1313 Bedford Avenue, Brooklyn, N Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and interest to our readers.

REVIEWED

Biological Aspects of Infectious Disease By F M Burnet, M D. Octavo of 310 pages, illustrated. New York, The Macmillan Company, 1940. Cloth.

In this book the author presents a general survey of infectious disease and of the agents that cause it, as well as the defenses that the body has developed to combat it. His approach to the problem is from the broad point of view of the biologist trained to see the "ecologic" problems involved and, in particular, the importance of consideration of the nature and activities of pathogenic microorganisms as they fit into the scheme of living things.

The tremendous research activity that has followed Pasteur's revolutionary discovery of the germ theory of infectious diseases has been naturally directed to the solution of the etiology and specific prevention and therapy of these morbid entities. Until recently, the possibilities of a more broad biologic approach have been less explored. Yet none will be apt to question the value of the point of view that sees infectious disease as a product of the struggle between man and microorganism of the "same order as many other types of competition between species in nature" and, thus, a "manifestation of the interaction of living things." Like every other living organism, pathogenic bacteria thrive at the expense of other forms of life. In the search for food on which to multiply, every nook and corner of the earth that can be exploited for a livelihood is filled. The host-parasite relationships thus established have far-reaching importance and significance, and the laws that govern them are yet most incompletely understood. While it appears evident that a balance or equilibrium has been developed over centuries, concerning this we have little information as yet.

The book, therefore, is a stimulating treatise and one that should appeal to a wide variety of readers.

As now seems necessary, many authors have contributed to this book which is recognized as one of the standard works.

W E McCOLLOM

Manual of Physical Diagnosis with Special Consideration of the Heart and Lungs. By Maurice Lewison, M D, and Ellis B Freilich, M D. Octavo of 317 pages, illustrated. Chicago, The Year Book Publishers, Inc. 1941. Cloth, \$3.00.

This new manual of physical diagnosis is a highly satisfactory introduction to this important art. It is concise, complete, and well written, and its extremely reasonable price will commend it to medical students. Nothing important is omitted which may be found in larger volumes covering the same material. A special word of praise should be given to the authors for avoiding the temptation to add extraneous material properly belonging in works on laboratory diagnosis. This often clutters up manuals of physical diagnosis adding unnecessarily to cost and bulk. There are 75 illustrations, all with the exception of Fig. 59 are well chosen and well printed.

MILTON PLOTZ

The Periodicity and Cause of Cancer, Leukemia and Allied Tumors. With Chapters on Their Treatment. By J H Douglas Webster, M D. Octavo of 178 pages. Baltimore, Williams & Wilkins Company, 1940. Cloth, \$3.50.

Contrary to the popular opinion that the usual course of neoplastic tumors is a steady progressive one, the author offers evidence of alternations of active and quiescent phases in tumors that assume a periodicity—a time pattern. He believes this to be a fundamental and intrinsic characteristic of neoplastic tissue which is evident in both primary and recurrent tumors.

A statistical analysis of 820 cases shows this characteristic in 96 per cent. Clinical examples are presented in a clear outline form.

The second part of the book discusses the theories of cancer and the physical, biologic, and pathologic basis of periodicity. The author offers this as proof of the virus theory for cancer.

HARRY MANDELBAUM

Plague On Us. By Geddes Smith. Octavo of 366 pages, illustrated. New York, The Commonwealth Fund, 1941. Cloth, \$3.00.

This is a text for the layman in which some facts and theories about communicable disease are presented and discussed in an interesting manner.

Clinical diseases are presented with a short historical summary and brought up to date in such a way as to stress their exact nature. Throughout the book the importance and the role of causative organisms, the host, and the environment are stressed, and the necessity for minute investigation and research for the final solution of some of the problems involved is emphasized.

The text is written in good style, it is easy reading, and its 350 pages will be found extremely interesting.

E R. MARZULLO

Bone Graft Surgery in Disease, Injury, and Deformity By Fred H. Albee, M.D. Octavo of 403 pages, illustrated. New York, D Appleton-Century Company, 1940. Cloth, \$7.50.

In this book the wide scope of bone graft surgery is presented by a pioneer in this field. The principles of bone grafting and its application to disease, trauma, and deformity is fully covered. The text is amply and adequately supplemented with roentgenograms of the various autogenous bone grafting procedures and with numerous excellent diagrams illustrating the author's ingenious methods of preparing and applying the various types of bone grafts to pathologic conditions. Throughout the text the author's operative technique for the bone grafting operations is clearly described. His arguments in favor of the use of the bone graft in its many indications and of the superiority of the tibial graft are clearly and convincingly presented. Although one might take exception to the use of the bone graft as a means of expediting rehabilitation in fresh fractures of the spine, the opinions in general expressed by the author throughout the book are sound and have stood the test of time. The book is divided into nine chapters, covering comprehensively the general principles of bone grafting, armamentarium of the orthopedic surgeon, spine fusion, bone graft surgery of the hip joint, bone graft surgery of ununited fractures, bone graft surgery for replacement of bone, plastic bone graft surgery, arthrodesis of bone graft operations, and bone block operations. The chapters on the general principles of bone grafting and bone graft surgery of ununited fractures are exceptionally interesting and illuminating. It is a complete treatise on the bone grafting phase of orthopedic surgery and is written by a surgeon who has not only pioneered in this type of work but has developed it to its present stage of perfection through years of experience. The book is a tribute to the author and is an indispensable addition to the library of the orthopedist.

L. GASTON PAPAE

Roentgen Interpretation By George W. Holmes, M.D., and Howard E. Ruggles, M.D. Sixth edition. Octavo of 364 pages, illustrated. Philadelphia, Lea & Febiger, 1941. Cloth, \$5.00.

This is the sixth edition of a text book on x-ray diagnosis. The great demand for the previous editions indicates the popularity of this work over a period of years, and this, the latest edition, offers all of the past contents and many new features. Dr. George W. Holmes, one of our most outstanding American radiologists, has kept the book up to date since the untimely death of its co-author, Dr. Howard E. Ruggles.

The subject matter is comprehensive, and all branches of the specialty are included. To compensate for thoroughness of detail, which can scarcely be anticipated in a book of 355 pages, there is an excellent bibliography at the end of each chapter to which the student may refer for further information.

The general plan of presentation remains the same as heretofore, and the eleven chapters of the first edition still appear, chapters having been altered as additional knowledge has come to light.

Medical diagnosis of today is considerably handicapped without modern x-ray studies, so that any student or practitioner who would acquaint himself with the general value of roentgenology would do well to digest thoroughly the subject matter of this book.

MILTON G. WASCH

Spermatozoa and Sterility: A Clinical Manual By Abner I. Weisman, M.D. Octavo of 314 pages, illustrated. New York, Paul B. Hoeber, Inc., 1941. Cloth, \$5.50.

Dr. Dickinson in the foreword to this volume epitomizes the *raison d'être* for a text such as this when he states: "No change in the medical-social field has been more rapid than the recent allotment of a large share in sterile mating to the male partner." The author throughout the text has evaluated the role of the male in the barren marriage.

Dr. Weisman clearly discusses and evaluates the various constituents of the seminal fluid, its physical and chemical properties, the methods of analysis, and the interpretation of the morphology of the sperm population.

The text is easily read, precise, and well illustrated. Although intended primarily for the general practitioner, some of the author's techniques in spermatozoa study, particularly that of the aspiration method for the recovery of spermatozoa from within the uterus or fallopian tubes and artificial insemination, can hardly be recommended as procedures for the "family physician."

The discussion of the female factor in the problem of sterility is concise, clear, and ample for a volume such as this is intended.

There seems, however, to be a paucity of the author's clinical experience and results with the various endocrine products as well as with artificial insemination. The bibliography of the relevant literature is up to date and unusually complete. The book is well recommended to all who are interested in the problem of human reproduction.

SAMUEL L. SIEGLER

Lipidoses: Diseases of the Cellular Lipid Metabolism By Siegfried J. Thannhauser, M.D. Edited by Henry A. Christian, M.D. Octavo of 370 pages, illustrated. New York, Oxford University Press, 1940. Cloth, \$8.00.

Here is a sound authoritative volume on that complicated group of diseases involving cellular lipid metabolism. The author has the happy faculty of clear expression and exposition, and his material is arranged in an orderly fashion. He has done much original work on the chemistry of the lipids which is included in the first chapter. Schuller-Christian's disease, Gaucher's disease, and the Niemann-Pick' syndrome are well described and brought up to date in relation to the newer knowledge in cellular lipid metabolism. The reviewer does not hesitate to recommend this volume not only for its general interest to internists but also because of its great value as a book of reference.

EDWIN P. MAYNARD, JR.

Criminal Youth and the Borstal System By William Healy, M.D., and Benedict S. Alper. Octavo of 251 pages. New York, The Commonwealth Fund, 1941. Cloth, \$1.50.

This book is a timely one because there is a growing realization that our present methods of treating young criminal offenders are not adequate. The authors present the Borstal System as the best method of rehabilitating young people who have come in conflict with the law.

The system itself has been worked out in Borstal, England, and is considered by many criminologists the best method of dealing with youthful offenders. The organization, personnel, and the day-by-day life in various Borstal institutions is effectively portrayed by the authors, so that one may contrast the methods used there with those in our own penal institutions. The Borstal System is considered more humane and corrective and is said to lower the incidence of readmissions to penal institutions.

The book is an excellent exposition of the treatment of juvenile delinquents and deserves the careful attention of all who are associated with this type of work. It is to be particularly recommended to sociologists, psychiatrists, and criminologists.

JOSEPH L ABRAMSON

The Medical Clinics of North America. May, 1941. Volume 25, Number 3 (New York Number) Octavo. Illustrated. Philadelphia, W B Saunders Co., 1941 (Six numbers a year). Cloth, \$16 net, paper, \$12 net.

A number of helpful articles appear again in this latest number of the *Medical Clinics of North America*. Robert Frank discusses homonology critically, Studdiford has a good paper on puerperal sepsis. There is a fine review of psychiatry by Lichtenstein and a useful note on therapy by Wortis. There are, in addition, several fine papers on practical endocrine subjects.

ANDREW M BABEY

Natural Resistance and Clinical Medicine. By David Perla, M.D., and Jessie Marmorston, M.D. Quarto of 1,344 pages. Boston, Little, Brown and Company, 1941. Cloth, \$10.

This is an admirable and unique work crammed full of a wealth of knowledge dealing with the subject under consideration. Based on the results described in more than 5,000 contributions to scientific literature and the combined researches of the authors, it embodies a broad survey of resistance and its relation to medicine. The completeness of its scope is manifested by a glance through its table of contents, which includes phases, such as heredity, age, sex, role of endocrine glands, humoral and cellular mechanisms, liver, body surfaces, and nervous systems, diet, certain depression states, and climates in their relationships to resistance. The final section deals with the clinical aspects of resistance.

In each section the theme is treated systematically and scientifically, with detailed and full citations of the literature. A mass of pertinent facts of work gathered in comparative research from plant life, as well as from innumerable species of the animal kingdoms, thus has been made available in compact form. These have been arranged so that the reader gradually arrives at a summation in which the authors' conclusions and the application of them have

been clearly and lucidly presented. Each chapter is finished with a summary and bibliography. The text is supplemented by many graphs and tables, but strangely enough no illustrations adorn the text. It would be impossible to review this monumental treatise in its entirety, since the subject matter covers so vast a domain. It shows the earmarks of painstaking and careful research both in the laboratory and in the library. Neither the progressive physician nor the scientist in the laboratory, be he a physician or lay individual, can afford to be without this work, since it touches in every phase of medical progress all the fields that deal with resistance to disease and the maintenance of health and life itself. It is a worthy monument by an indefatigable worker who sacrificed himself for humanity, and by his helpmeet who was a partner with him in this full contribution to our knowledge.

MAX LEDERER

Clinical Pellagra. By Seale Harris, M.D. Quarto of 494 pages, illustrated. St. Louis, C V Mosby Co., 1941. Cloth, \$7.00.

In the pages of this volume will be found a great deal of useful information about pellagra. The early works are faithfully recorded and generous credit is given to the pioneer students in England and Italy who described the disease at least seventy-five years before the first cases were recognized in the United States. It was not until 1910 that the disease had become a serious problem in the south. The earlier theories as to the cause of the disease are gone into in detail, so much that some of the material becomes repetitious. The reader also gains the impression, perhaps erroneously, that the book reflects some of the rivalries, personal and sectional, that arose during the search for the cause and cure of pellagra. All this makes the volume longer than it need be. Nevertheless, the student and practitioner can find what he wants about the present state of our knowledge with specific directions as to the treatment of this disease. The working bibliography at the end of the book should prove useful.

EDWIN P MAYNARD, JR.

Introduction to Psychobiology and Psychiatry. A Textbook for Nurses. By Esther L Richards, M.D. Octavo of 357 pages. St. Louis, C V Mosby Company, 1941. Cloth, \$2.50.

This book is primarily intended as a textbook for nurses. As such, it misses the mark, since we doubt that the average nurse without any preliminary knowledge of psychiatry will be able to follow intelligently the author's exposition. The author, who is a disciple of Dr Adolf Meyer, presents the material from the standpoint of the psychobiologic concepts of Dr Meyer and stresses the need for personality studies. The questionnaire method evolved by Dr Meyer is used to help the nurse determine her qualifications for nursing.

The author is inclined to be verbose, but the material has been well presented. The book is better suited for the general practitioner who desires to learn something of psychiatry and psychobiology than for the average nurse.

THE NATURAL MINERAL WATERS OF SARATOGA SPA ARE OWNED AND BOTTLED BY THE STATE OF NEW YORK

SARATOGA SPA
GEYSER WATER

to
Stimulate the Secretory Action
of the Stomach

The medicinal Waters of Saratoga Spa, by reason of their natural carbonation, are stimulating to the mucous membranes of the upper gastrointestinal tract

Of the three Spa Waters, bottled by the State, Saratoga Geyser — the alkaline-saline — is first in consideration for the above-mentioned purpose It is bland, exceptionally palatable, yet richly mineralized Its natural supersaturation with CO₂ makes it an appetizing and refreshing beverage

Geyser Water is indicated for conditions where the physician desires to fortify the alkaline reserve, and to stimulate the secretory activity of the stomach Patients with poor appetites and many in the rheumatic group are included here

Geyser and the other Spa Waters for internal use are discussed in Spa Publication No 9—of which a copy will be sent gladly, on request For clinical trial a 4-bottle Physician's Sample assortment will also be sent if you wish Write, on your professional letter-head, to W S McClellan, M D, Medical Director, Dept 155, Saratoga Spa, Saratoga Springs, N Y

[Continued from page 1686]

From Thirty Years with Freud. By Theodor Reik. Translated by Richard Winston. Octavo of 241 pages. New York, Farrar & Rinehart, Inc., 1940. Cloth, \$2.50.

The author is well qualified to write about Freud and his work since he was associated with Freud for thirty years. Because of this he brings to us many intimate facts about the founder of psychoanalysis.

The first part of the book deals with Freud and his followers. This and the preface afford us many details of Freud's life which have not generally been known.

For the common reader this portion of the book will be most interesting, especially when the author gives some intimate anecdote of Freud, and presents him as a warm, likeable human being, rather than merely a name.

The latter part of the book deals with Freud as a critic of our culture. Here is included psychoanalytic interpretations, which are rather difficult to follow except for those versed in psychoanalysis. Further, when the author finds it necessary to come to the defense of psychoanalysis and indulges in psychoanalytic terminology, the book will be found rather dull by the average reader. However, the psychoanalyst and the psychiatrist will undoubtedly find much of value in the discussions by the author. This is especially so because there is included an unknown lecture of Freud's.

One wishes that the author had included more information concerning his personal contacts with Freud, so that we might have a more complete record of an individual who is almost legendary and who has been a source of so much controversy in the psychological world. Lay people, as well as medical men, would enjoy knowing more of Freud as a man. On the whole, however, the book adds something to our knowledge of Freud, though his complete biography remains yet to be written.

J. L. ABRAMSON

Anus, Rectum, Sigmoid Colon. Diagnosis and Treatment. Second edition. By Harry E. Bacon, M.D. Octavo of 857 pages, illustrated. Philadelphia, J. B. Lippincott Company, 1941. Cloth, \$8.50.

Seventeen months after its first printing, this book is in its second edition. The literature has been covered most thoroughly as evidenced by the voluminous bibliography which is appended at the end of each of the twenty-four chapters. Although different views and methods are outlined for various disorders the author indicates his choice and the reason for so doing, and he concludes practically every chapter with a summary of treatment.

New illustrations have been incorporated in the present edition, and some of the older ones have been replaced by new figures. In addition to that, new material has been added, such as Devine's defunctioning colostomy and the sulfanilamide treatment of chronic ulcerative proctosigmoiditis and in the sequela of lymphogranuloma venereum.

Although the author employs the term "lymphogranuloma venereum" in the preface to the second edition, it does not appear in the index—the term "lymphopathia venereum" is used in-

stead. This will undoubtedly be remedied in a later edition.

As the present reviewer stated in his review of the first edition "An awakening to the realization of the magnitude of the subject of proctology is in store for those who acquire this book. It should prove of inestimable value to anyone interested in the subject of proctology."

A. W. MARTIN MARINO

Practical Neurological Diagnosis with Special Reference to the Problems of Neurosurgery. Second edition. By R. Glen Spurling, M.D. Octavo of 239 pages, illustrated. Springfield, Charles C. Thomas, 1940. Cloth, \$4.00.

The first edition was well received. In his second edition Dr. Spurling has adhered to the aim of his first work, viz., "to present a simple account of the principles of neurological diagnosis."

The subject matter is presented in simple, clear, concise fashion. Obscurity of statement is avoided by the orderly, logical, if somewhat dogmatic, method of statement. Emphasis is placed on the physical examination. Above all, the proper manner of eliciting findings is stressed, and a detailed description of how each test should be performed is given. The early student and general practitioner of medicine will be delighted with this small compact volume.

HAROLD R. MERWARTH

The 1940 Year Book of Pathology and Immunology. Pathology edited by Howard T. Karsner, M.D., and Immunology edited by Sanford B. Hooker, M.D. Duodecimo of 688 pages, illustrated. Chicago, The Year Book Publishers, 1940. Cloth, \$3.00.

This is the most recent of the Practical Medicine Year Book Series, being the first attempt at publication dealing with these two subjects. The field of pathology is ably reviewed by Dr. Howard T. Karsner, professor of pathology, Western Reserve University, Cleveland, and that of immunology by Dr. Sanford B. Hooker, professor of immunology, Boston University School of Medicine.

This volume follows the same general form of the current series. It meets the need of the laboratory physician, who will welcome the terse but comprehensive reviews of both compilers, as well as the needs of the various specialists who in the course of their medical contacts feel the necessity for an up-to-the-minute review of advances being made in laboratory fields. For both these reasons the volume possesses practical, as well as educational, value to every physician.

One pleasant feature of this issue, which sets it apart from any other abstracted or condensed review, lies in the comments of the editors in the form of pertinent and critical footnotes.

The section on pathology, because of the nature of the subject, more readily lends itself to the use of illustrative material. The photographs of gross and microscopic specimens are unusually faithful reproductions.

The volume can be highly recommended to a prominent place in the doctor's bookshelf of current reviews.

THEODORE S. CURPHEY

[Continued on page 1690]

Hospitals and Sanitariums

Institutions of Specialized Treatments

VISITING DAY FOR PHYSICIANS

Sanitariums have been in existence for so many years that it is to be expected that private practitioners may well take them for granted. True, many physicians perhaps have during the earlier years of their careers, visited one of these institutions to see what one was like. They may have done so with a purpose in mind and an anticipation of having to refer a patient to some sanitarium some future day.

But times have changed and with them, so have the sanitariums. The sanitarium of 1910, 1920 or even 1930 is as incomparable with our modern institution as a vehicle of today is with the vintage cars of two or three decades back.

The sanitarium that our more mature physicians may remember inspecting when their futures were still an enigma, would hardly be the place they would send patients today had it not kept pace with the progress of treatment.

The improvements in methods of receiving patients, treating them and caring for them in every way to complete the work of the family physician are interesting as well as practical from the standpoint of modern medicine.

Young physicians, too, would gain a lot of invaluable information about sanitariums if they would take a little time out to study personally the several types of institutions that can be of service to them and their patients.

Of course, you do not personally analyze every brand of medicine you prescribe, so it might seem a little inconsistent to do that very thing in the matter of places where a convalescent or a chronic might be sent. In the medicine, however, you know it has all the ingredients required to treat the particular illness of your patient. In sanitariums there are many "ingredients" that you are sure of as well, yet you would find many more things to impress you and instill confidence if you could see them in actual operation.

There is a visiting day for you at any accredited sanitarium—any day—and the staff will welcome you at any time, gladly, to show you their institution and all its recommendable features.

It might be an idea, on your next motor trip into the country to look up one of the JOURNAL advertisers in the sanitarium section. It will be worth the half an hour or so that you squeeze out of a brief day off.

Lectures on Diseases of Children By Sir Robert Hutchison, M.D., and Alan Moncreiff, M.D. Eighth edition. Octavo of 471 pages, illustrated. Baltimore, Williams and Wilkins Co., 1940. Cloth, \$6.75

This is the eighth edition of a practical and an original work on pediatrics. It contains a collection of lectures on various diseases and conditions of interest to all who handle babies and children in their practice.

The chapters on rickets, the clinical examination of the child, behavior problems, rheumatism, constipation, and tuberculosis, deserve special mention.

In a general way it may be said that this is the work of two men who must have had a tremendous amount of clinical experience with children. However, in order to conserve space and in the attempt to keep the pages down to a given number, in order to make this book compact while at the same time mentioning as many disease entities as possible, the authors were forced to omit the necessary detailed information that would make this book more serviceable to pediatricians as well as to the general practitioner.

HARRY APFEL

The Endocrine Function of Iodine By William T. Salter. Octavo of 351 pages, illustrated. Cambridge, Harvard University Press, 1941. Cloth, \$3.50

The author makes a successful effort to show that iodine is a bridge between biochemistry and endocrinology. As such, he formulates a concept that there is an endocrine balance and that some hormones are either stimulants or antidotes, thus preserving health and personality and keeping this balance well poised. This he arrives at by a careful study of the iodine content of all glands and their interrelationship.

The book, although scientific and technical, is written in popular form. The newer iodine studies are particularly directed toward a differentiation between inorganic iodine content and the thyroid hormonal iodine content in the blood and tissues. From his studies he concludes that the circulating blood iodine content can be of diagnostic value in distinguishing thyroid disease and other related glandular conditions.

This book is a valuable addition to the studies of endocrine and metabolic diseases and is highly recommended by the reviewer.

MORRIS ANT

The Mask of Sanity: An Attempt to Reinterpret the So-called Psychopathic Personality By Hervey Cleckley, M.D. Octavo of 298 pages. St. Louis, C. V. Mosby Company, 1941. Cloth, \$3.00

The book, as its subtitle implies, is an attempt to reinterpret the so-called psychopathic personality. While considerable progress has been made in understanding the nature and causes of mental disorders, very little has been discovered that would enable one to get a clear-cut idea of the mechanisms underlying the disorder that is generally called constitutional psychopathic inferiority. The law does not recognize this disorder as a disability limiting

legal responsibilities of people suffering from it. The various state hospitals cannot keep these people against their will because they are not committable in the usual sense of the term. The result is one of a chaotic condition resulting in disaster to themselves and untold misery and despair to their families.

The author presented several case histories in his attempt to describe these persons as they actually appear in life. He stresses the fact that a mask of perfect sanity conceals the real inward state of all persons so disordered. In view of the lack of serious attention given to this large number of mentally sick persons, the author calls attention to the fact that the psychopath stands today as the forgotten man of psychiatry.

The book is a splendid presentation of the subject by one who has had a large experience in psychiatry and who has given special attention to the psychopath. It is written in a lucid and arresting style, incisive and emphatic, so that when one begins to read the book one can hardly let go of it. It is a positive and a most valuable contribution to psychiatry. The author deserves credit for dealing so ably with such a difficult subject. It is recommended to all psychiatrists, sociologists, social workers, judges, and lawyers. It will find a wide circulation among all intelligent and socially minded people.

IRVING J. SANDS

Germes and the Man By Justina Hill. Octavo of 461 pages. New York, G. P. Putnam's Sons, 1940. Cloth, \$3.75

It is no easy matter to explain to the laity the remarkable discoveries of modern medical science, especially in such highly technical fields as those of bacteriology, immunology, and physiology. The author of this interesting book has succeeded remarkably well in describing not only many of the pathogenic bacteria and their mode of action in the human host but also the wonderfully complex mechanism by which the body defense operates. This is accompanied by an accurate account of the remedial measures that research has discovered, both for prevention and cure. While the book primarily concerns pathogenic bacteria and not viral infections, there are included also appropriate sections on the healing of wounds, and on germicides, disinfectants, and antiseptics.

Historical aspects of developments in our knowledge in all these important special fields are emphasized, and properly so, and attention is drawn to the parts that various contributors have played.

The subject matter is well selected and it is quite definitely abreast of the more recent work. Diligence and admirable care in bibliographic research are in constant evidence, and this, in conjunction with the 28 pages of bibliographic references, is a noteworthy innovation, which, it is to be hoped, will not go unnoticed.

While the author writes in an informal style, she has filled her book with instructive and useful information explaining technical terms in non-technical language. The statistical data included is of recent publication and well illustrates the point stressed. The many quotations are from the most recognized sources.

This is a volume that should not be read.

A "CURE" FOR INSOMNIA?

Perhaps not entirely new, but new on its larger scale of accommodations and availability to more "regular" people is the "Yacht Cruise" now currently popular.

Described as healthful, restful and interesting, these attractive inland water cruises last for six days, starting every Monday morning from Stamford, Connecticut, during July, August and September. The itinerary covers a sail on the sheltered waters of Long Island Sound, along the coasts of Long Island and New England to Port Jefferson, New London, Montauk, Duck Island Roads and back to Port Jefferson and Stamford.

A typical day includes

- 1 Bathing before breakfast, either off the side of the yacht or on the beach of the port
- 2 Breakfast with plenty to eat and a reasonable variety of "seafaring" wholesome foods
- 3 Up-anchor and farewells to neighboring yachts Under way for the day's run.
- 4 Eleven o'clock cup of bouillon.
- 5 Noon, heave to in deep water for expert swimmers to take a plunge before lunch
- 6 Lunch.
- 7 Under way again, with an opportunity for a nap in the cabin or a sunbath on the forward deck. Trolling in the towed life boat for those who wish to see how many big ones can get away from them, or if they can catch anything that will appeal to their own appetite and that of their shipmates
- 8 Four o'clock tea and cakes
- 9 A round of bridge, some other game, or a round-robin for membership in the tall story club
- 10 Supper after making port

11 Independent sightseeing around the Yacht Basin or about the town.

12 A beach fire and moonlight beach party with a hot dog and marshmallow roast. Sandwiches for those who are still hungry before turning in

No, it is not possible to do "a mile around the deck" on these yachts but there is good elbow room, comfortable and roomy "pullman" berths. Each yacht carries an experienced captain and stewardess, and accommodates from four to eight guests, making it possible for a group of friends or a family to have virtually a "private yacht" for a week's vacation.

The simplicity and ease of these cruises guarantee a real relaxing vacation, something doctors prescribe but seldom can be certain that the patient will take. Yet, there is sufficient activity to assure a healthful tiring of the body and sound restful sleep.

As the operators of these cruises say—"Insomnia will not be a shipmate."

Your travel agent or travel bureau will gladly furnish complete details. The cost is only \$60.00 for the entire cruise, meals and berth included of course.

lightly and then laid aside and forgotten. It deserves a place as a reference source for the average intelligent reader.

JOSEPH C. REGAN

Essentials of Dermatology. By Norman Tobias, M.D. Octavo of 497 pages, illustrated Philadelphia, J. B. Lippincott Co., 1941. Cloth, \$4.75.

Every now and then there is published a book combining all the elements that, when taken together, seem to make one wish it were of one's own making. Such a book is Dr. Tobias' handbook of dermatology, and the most certain way to enjoy it is to possess it, since it contains in the most comprehensive manner exactly what its title calls for—the essentials of the study and practice of dermatology.

Aside from containing the most up-to-date knowledge at present available in this era of intensive advancement, the author has taken great pains to cover each subject with sufficient fullness to provide the reader with a complete working knowledge as to the etiology, pathology and most approved methods of treatment. Under the title of "Herpes Zoster," Dr. Tobias has given well-deserved credit to the Ruggles treatment—the intravenous use of sodium iodide—first suggested by Dr. E. Ruggles of Rochester, New York, in the March, 1931, issue of the *Archives of Dermatology and Syphilology*.

Especially valuable to the student and general practitioner are the superb photographic illustrations which mean so much in the differentiation and correct diagnosis of diseases that are almost entirely objective in their symptomatology. The modern classification of diseases is helpful to the student, and the typography and general makeup of the volume is most commendable.

NATHAN THOMAS BEERS

An Introduction to Pharmacology and Therapeutics. By J. A. Gunn, M.D. Sixth edition. 16mo of 242 pages. New York, Oxford University Press, 1940. Cloth.

Gunn's well-written introduction to pharmacology herewith enters its sixth edition and, notwithstanding necessary revision, continues to remain a short, reasonably priced volume. It continues to serve its purpose well. It is not intended as a textbook and will probably find its widest usefulness in this country as "a book which a student can read in the vacation before attending lectures," as Gunn intended. The fact that this little volume is written by an Englishman should not deter anyone here from purchasing it, since U.S.P. equivalents are all given next to those of the British Pharmacopoeia.

MILTON PLOTZ

Schizophrenia in Childhood. By Charles Bradley, M.D. Octavo of 152 pages. New York, The Macmillan Company, 1941. Cloth, \$2.50.

The author is medical director of the Emma Pendleton Bradley home. In this book he has reviewed the subject of schizophrenia in children beginning with a historical survey of the literature. Prior to 1900, little if anything was

written concerning schizophrenia in childhood. Until 1925 the subject was discussed in Kraepelinian terms, which were applicable to adults as well as children. Since then, more significant contributions have been made by such authors as Meyer and Bleuler.

Over a period of eight and one-half years the author has observed 4 children under 13 with definite schizophrenic psychoses out of a total of 250 children admitted for behavior disorders.

In childhood, schizophrenia is two to three times more common in boys than girls. The diagnosis has been made in patients as young as 2½ to 4 years. The major symptoms are diminished interest in the environment, emotional disturbances, symptoms of regression to more immature and simpler levels of interest, alterations of motor behavior, speech disturbances, disturbances of thinking—overt behavior such as seclusiveness, day dreaming, diminution in number of personal interests, and physical inactivity, and hallucinations and illusions.

There are subsequent chapters on the etiology of the disease which is still unknown. Electroencephalography has afforded a new approach in laboratory diagnosis of this disease, although no specific pattern has yet been evolved. Psychologic studies have been done and indicate a progressive lowering in the I.Q., with better results on tests of speed than those of accuracy and better verbal than performance material.

There is a list of essential points for diagnosis. The prognosis is uniformly bad. The final chapter concerns itself with the practical concepts of childhood schizophrenia. There is also a bibliography.

This book should be profitable reading for the profession.

STANLEY S. LAMM

Strange Malady. The Story of Allergy. By Warren T. Vaughan, M.D. Octavo of 268 pages, illustrated. New York, Doubleday, Doran & Co., 1941. Cloth, \$3.00.

In this work the author seeks to help the inquiring patient to understand the peculiar nature of his allergic illness and to comprehend the immunologic basis of his "strange malady." Unlike most of the other books of this type it is written for the intelligent reader and is not too elementary.

Interspersed with theoretic material are interesting case histories, witty comments, and clever illustrations. These capture and hold the reader's interest in a subject that, under ordinary circumstances, is technical and boring to the lay individual.

An interesting historical section introduces the subject. The author then deals with the recognition, treatment, and prevention of the various allergic conditions. An excellent section on allergens and their hidden sources of contact is included.

The author leans heavily on Ehrlich's side-chain theory for the explanation of the immunologic phenomena in allergy. Clever diagrams and sketches illustrate these theoretic concepts. Certain liberties are taken with the side-chain theory for the sake of clarity and interest in presentation, but the end achieved justifies these infractions of scientific fact.

ENJOYING MEDICAL REGIMES

Physicians often meet "a patient" who enjoys being ill (or pretending illness), but as a rule, no one enjoys a medical régime Or are we wrong?

In his book, *Diet and Pleasure*, Paul Rebdux almost convinces his readers that illness is not such a bad experience after all. In his chapter "I Must Take a Dose," the author remarks

"As I said in the beginning of this book, it is not so unpleasant to be ill as is often pretended First, you feel an uneasiness against which you fight You tell yourself that you are energetic You do not want to take care of yourself You snap your fingers at fever At last you give in to the persuasion of those who care for you Very well, call the doctor The doctor arrives He feels your pulse, looks at your tongue, leans his head on your stomach, and prescribes something for you.

(Continued on page 1695)

"The doctor must prescribe something, otherwise you would consider the fee he asks for his visit insolently excessive In public opinion, those who have nothing prescribed for them cannot be ill. And it is revolting for people who are not ill to have to pay for the doctor's visit Only a great specialist, honored and influential, is able to relieve the patient's family by saying, 'There is nothing the matter with you, sir' If anyone else talked like this he would lose his practice"

Having absolved the medical profession from having to humor patients and their immediate relatives, Rebdux settles into the subject of taking a dose

"The taking of a dose," he muses, "can be considered as the essential and practically the only disadvantage of an illness I do not mean, of course, a serious illness

"The advantages, on the contrary, are numerous At

Shortens the duration of the cough relieves the distressing spasms and gives the child rest and sleep. Also valuable in other PERSISTENT COUGHS and in BRONCHITIS and BRONCHIAL ASTHMA In four-ounce original bottles. A teaspoonful every 3 to 4 hours.

GOLD PHARMACAL CO., New York

Say you saw it in the NEW YORK STATE JOURNAL OF MEDICINE

[Continued from page 1692]

The deft personal touch of the author and his informal method of presentation contribute much to make this book a success. It will furnish absorbing and instructive reading to the physician as well as to his intelligent patients.

MATTHEW WALZER

How to Prevent Goiter By Israel Bram, M.D. Octavo of 182 pages, illustrated. New York, E. P. Dutton & Co., 1941. Cloth, \$2.00.

The purpose of this book is to "set forth the simple rules of physical and mental conduct which help prevent disturbances of the thyroid." The text contains a great deal of general information and advice for the potential and mildly hyperthyroid patient. However, it is not offered as a substitute for the physician. Perhaps the most redeeming features are the repeated warnings to the layman of the dangers of self-medication by the use of thyroid extract and iodine in any and all forms of goiter. Chapter VIII by Dr. Robert Oleson, senior surgeon, United States Public Health Service, on "Endemic Goiter" is, in the reviewer's opinion, one of the best chapters. Dr. Oleson warns against the wholesale administration of iodine prophylaxis. Individualized treatment rather than routine "wholesale methods" are stressed even in so-called "goiter belts."

The author's rationalization regarding the "Prevention of Tumor Goiter" leaves much to be desired. He is on safer ground when he discusses "Prevention of Malignant Goiter."

Perhaps the weakest parts of the text are Chapters XI to XIV, dealing with Graves' disease (exophthalmic goiter). The impression is conveyed that surgical intervention in Graves' disease should be the exception, rather than the rule. Dr. Bram evidently has more faith than the reviewer in so-called medical treatment of hyperthyroidism.

The text is written primarily for the patient and hence is not recommended for the physician.

ARTHUR GOETSCH

The Parasites of Man in Temperate Climates. By Thomas W. M. Cameron. Octavo of 182 pages, illustrated. Toronto, University of Toronto Press, 1940. Cloth, \$3.00.

The author has succeeded in compressing a large amount of useful information about animal parasites into the limited compass of 182 pages. The book is designed for the practitioner and not for the student of tropical medicine or the parasitologist. To gain brevity and to simplify the subject for the man in general practice, a didactic style is followed which, in places, leads the author into direct misstatements. One example is the statement on page 17 that *Endamoeba coli* never contains engulfed red blood cells, another, that *Plasmodium vivax* is the only species used in induced malaria for pyretic purposes (page 23). The general practitioner is usually in search of detailed practical information on clinical diagnosis and treatment. In the present volume these subjects are not always adequately presented.

The illustrations are good but for the most part lack keys to the magnification used. The bibliography is brief but useful. A glossary

would spare the practitioner the necessity of referring to a medical dictionary for the meaning of terms such as "strigeid" (p. 37).

In summary, this reviewer feels that in certain important respects the volume fails to achieve its proclaimed purpose—to give the practitioner information he requires—but it is helpful to have the subject summarized as Professor Cameron has done and future editions will be looked for with interest.

ELLISTON FARRELL

Williams Obstetrics. A Textbook for the Use of Students and Practitioners. By Henricus J. Stander, M.D. Eighth edition. Octavo of 1,401 pages, illustrated. New York, D. Appleton-Century Company, 1941. Cloth, \$10.

In this eighth edition of *Williams Obstetrics*, Stander comes into his own, for this standard textbook has been almost completely rewritten and now reflects his own student teaching at Cornell. Three new chapters have been added—those on diseases and abnormalities of the newborn, contracted pelvis, and sudden death and maternal mortality.

The chapter on puerperal infection written by Douglas is extraordinarily good and easily is the best and clearest exposition of this topic that we have ever seen. The toxemias of pregnancy are classified as recommended by the American Committee on Maternal Health. It is interesting to note that Stander has not yet abandoned his "low reserve kidney." His great interest in the biochemistry of eclampsia continues. The text on classification of pelvis with the new roentgenography is excellent.

The entire book is excellent typographically with beautifully colored plates, sensible, orderly arrangement, a good index, and exceptionally complete and live bibliographies. Though Stander says that he had approached the first revision of *Williams' textbook* some six years ago "with some hesitation, and a certain amount of misgiving," that edition was an excellent textbook on obstetrics for medical students, practitioner, and specialist. This one is better and is highly recommended.

CHARLES A. GORDON

Applied Neuroanatomy. Part I—The Spinal Cord. By Rafael Hernandez, M.D. Quarto of 123 pages, illustrated. Nashville, Tennessee, Elm Hill Road and Arlington Avenue, The Author, 1941. Paper, \$3.50.

The book is the outgrowth of a series of lectures which the author has delivered to medical students in his capacity as professor of neurology at Meharry Medical College, Tennessee. It differs, however, from the usual book of this type in that the author has attempted to correlate clinical neurology and neuroanatomy.

The book is profusely illustrated with original drawings which definitely enhance its value. Controversial subjects have been treated lightly, but an adequate bibliography has been appended for those who care to follow the various subjects in greater detail.

In order to make the book more economical and within the financial means of the student, a special format (lithoprinting) has been used. This in no way detracts from the usefulness and

last you have time to read difficult authors, such as Marcel Proust. You can read the old books you loved in youth. Daudet, Zola, or the elder Dumas. You can rout the importunate by a telephone message to the effect that you are ill. You need not answer letters. And, lastly, you can watch people hurrying by the window to places they dislike, on business that bores them, while you remain at home, beautifully warm in bedroom slippers beside the fire, fed on light dishes, drinking delicious drinks redolent of woods and fields."

But, sums up this author

"Alas! however slight these illnesses may be, there is always the same disadvantage

"A little purge will do you good," said the doctor."

Rebdux then suggests a means of taking a purge without too much unpleasantness. He suggests trying the principle of giving the papillas an anesthetic—with above all things, *cognac*.

And perhaps that is his prescription for enjoying medical régimes

value of the book. It can be highly recommended to medical students and to all practitioners who desire a comprehensive, concise, fundamental knowledge of neuroanatomy.

JOSEPH L. ABRAMSON

The Avitaminoses. The Chemical, Clinical, and Pathological Aspects of the Vitamin Deficiency Diseases. By Walter H. Eddy, Ph.D., and Gilbert Dalldorf, M.D. Second edition. Octavo of 519 pages, illustrated. Baltimore, Williams & Wilkins Co., 1941. Cloth, \$4.50.

This excellent work covers not only the subject of avitaminoses as the name implies, but the entire subject of vitamins, their chemistry, pathology, function, clinical effect of mild and extreme deficiencies, and how to prevent or treat them.

The chapter on cellular oxidation clarifies for those not already familiar with the subject the role that vitamins play in metabolism. In the chapter on vitamin requirements, vitamin D dosage on which a vast literature exists is treated rather superficially. The authors realize the difficulties encountered in trying to correlate experimental evidence on animals with clinical application of that evidence in man. They realize, too, that the vitamin control of food depends on a variety of factors—source of supply, method of transportation and storage, and preparation for human consumption.

This is a fine book which must have required a tremendous amount of painstaking and co-ordinated effort. It should be a favorite with the clinician as well as the biochemist. For the benefit of those who desire further information a voluminous literature is appended to each chapter.

BENJAMIN KRAMER

Hemorrhagic Diseases. Photo-Electric Study of Blood Coagulability. By Kaare K. Nygaard. M.D. Octavo of 320 pages, illustrated. St. Louis, C. V. Mosby Company, 1941. Cloth, \$5.50.

Nygaard is a pioneer who in this monograph makes a herculean effort to depict graphically the much complicated coagulative mechanism not unlike the electrocardiogram.

These graphs are produced photoelectrically as fluid blood changes to solid blood. A well-ordered apparatus does the trick. A knowledge of mathematics, physics, biology, and chemistry is essential to a thorough understanding of this valuable treatise. The book is, therefore, recommended to advanced students of the coagulation problem and should grace the shelves of all research laboratories. It is thoroughly inspiring.

MAURICE MORRISON

Psychiatric Dictionary with Encyclopedic Treatment of Modern Terms. By Leland E. Hinsie, M.D., and Jacob Shatzky, Ph.D. Octavo of 559 pages. New York, Oxford University Press, 1940. Cloth, \$10.50.

This is a medium-sized book of 559 pages. As the title indicates, it is devoted substantially to psychiatric terms and expressions, but it also includes terms found in related fields—namely, neurology, constitutional medicine, genetics and eugenics, mental deficiency, forensic psychiatry,

social service, nursing, and occupational therapy—in all, about 7,500 definitions. The names of individuals outstanding in their respective fields are given with pertinent facts relative to their theories and accomplishments. The span of time covered is from Hippocrates up to the present. With the manner of treatment and numerous cross references and guides to pronunciation one finds this dictionary convenient for quick reference. It can be recommended.

A. E. SOPER

Born That Way. By Earl R. Carlson, M.D. Duodecimo of 174 pages. New York, John Day Company, 1941. Cloth, \$1.75.

This book is an autobiography of one individual's successful attempt to overcome the handicap of an injury at birth through painstaking perseverance. Dr. Carlson is one of the best known authorities on the care of cerebrospastic children. His work at the Columbia Medical Center has won him national fame.

In the present work the author relates his experiences from childhood through adult life. This book is of particular interest to doctors because there are suggestions, made by the author from his own experiences, which, if carried out by the physician, would make for marked improvement on the part of the patient suffering from cerebrospastic paralysis.

STANLEY S. LAMM

The New International Clinics. Original Contributions, Clinics, and Evaluated Reviews of Current Advances in the Medical Arts. Edited by George M. Piersol, M.D. Volume I, New Series Four. Octavo of 304 pages, illustrated. Philadelphia, J. B. Lippincott Company, 1941. Cloth, \$3.00.

The feature of this issue of *International Clinics* is a symposium of medical clinics from the Yale School of Medicine. All of these clinics and the review of the present status of immunization procedures for the prevention of certain communicable disease by Veeder and Rohlfing are excellent. The original contributions, with the exception of a long-winded and weirdly contributed article on cerebral malnutrition, are well up to the high standards set under the editorship of Dr. Piersol.

MILTON PLOTZ

Textbook for Male Practical Nurses. By Gayle Colman, R.N. Duodecimo of 215 pages. New York, The Macmillan Company, 1941. Cloth, \$2.00.

This book is written primarily for male practical nurses, but the information it contains is useful to anyone who is entrusted with the care of a patient, whether in a hospital, sanitarium, or at home. The hospital and its component departments are described. The proper procedures to follow in the care of the patient from the time the patient enters the hospital to his discharge are carefully and accurately outlined.

Everything in the care of the sick to increase the patient's comfort and relieve his distress is described. This book contains the principles of good nursing for all of those who take up nursing for their life's work.

NUMBER 17

Editorial

Sauce for the Goose

The time is now at hand which will provide a real test of the temper of the American people, and perhaps also of the soundness of our more recently acquired institutions and customs. The only real sacrifices to date under the defense program have been made by the young men called into selective service, young physicians included.

There will be need from now on for willing sacrifice and self-restraint by everyone. Restrictions on the use of silk and gasoline are already in force besides many other priorities in raw materials, the effect of which is not so immediately felt by the public. But they will be felt, we have been exceedingly wasteful of the gifts of freedom by and large.

Now, by government regulation and for the common safety, we will have to do without—to economize in many ways to meet the threat of "absolutism tempered by assassination." That means increasing self-restraint on the part of everyone. But since the power to restrain is being increasingly granted to the government, it becomes more than ever an obligation of those entrusted with the far-reaching powers of regulation to use them wisely.

These increased powers are being accorded by the people to government for the sole purpose of *preserving our democratic system* and not at all with the intention that there shall be created thereunder a managed economy. For the duration of

any *real* emergency, during which all necessities must be subordinate to the defense effort, such grants of power are the indispensable tools of accomplishment and will be so considered by those who must bear cheerfully and willingly the brunt of the sacrifices in money and comfort necessarily entailed, as well as in a different way of life. But let the fact be clearly understood that these grants of power are mere proofs of the flexibility of the democratic way of life and in no way constitute a mandate to change the form or philosophy of our constitutional government.

Those physicians who, for the emergency, are willing to throw their all into the pot, abandon private for public medicine, and their associates who are cheerfully aiding without recompense the selective service, the civilian defense preparations, and all the other burdens of the emergency are doing so in the expectation that their representatives in Congress and those who administer the necessary regulations will subject themselves to the restraints they propose to require of others.

There is still an American ethos, a characteristic spirit of the Nation, it was born here, on the soil which we prepare to defend and for which any sacrifice will cheerfully be made. It must not be permitted to die by confusion of purpose, by the permanent abandonment of a philosophy of government which has

nurtured it About that let there be no misunderstanding "You have," said

Benjamin Franklin, "a Republic, if you can keep it"

What Price Human Life?

With nearly the entire world engaged in an orgy of unprecedented human slaughter on land, sea, and in the air and with this Nation busily engaged in the manufacture of the means to this end, mention of our domestic mortality rates may seem somewhat smug Nevertheless, in spite of an increase of about 17 per cent in automobile accidents, the mortality of the American people seems to remain at a favorably low level According to the *Statistical Bulletin* of the Metropolitan Life Insurance Company, for July, 1941, "the current year may fully be expected to rank among the years of minimum mortality" From the record of the first six months of the year of 1941, it "appears that there will be no less than seven in the list of selected causes of death that will establish new minimum rates scarlet fever, diphtheria, pneumonia, tuberculosis, diarrhea and enteritis, appendicitis, and puerperal diseases Also, diabetes, cerebral hemorrhage, and chronic heart diseases"

Dislocations of the population due to worker migrations associated with the defense effort, housing shortages, and sanitary insufficiency in many areas might have been expected to react unfavorably upon the record, especially for the respiratory diseases, but tuberculosis and pneumonia continue to present minimum rates The favorable record for pneumonia appears to be the result of

improved modern methods of treatment of this disease

The death rate for motor vehicle accidents, according to the *Bulletin*, has risen 26 1 per cent It has been higher each month this year than in the corresponding month of 1940 Canada has shown the same percentage increase, approximately, but with a lesser total Looking forward to the near future when the output of new passenger cars will be sharply curtailed, the prospect is anything but bright for an effective reduction of accidents and fatalities For this will necessarily mean the prolonged use of old vehicles with their worn brakes and mechanisms Even the prospect of gasoline rationing will not necessarily affect the future totals, except possibly temporarily

It is discouraging to contrast the meager salvage of human life by improved methods of treatment of disease by the slow and orderly progress of study and research with the criminally carefree and brutal destruction of well people by machinery Is it not a little ridiculous for supposedly intelligent human beings to point to a low mortality rate with pride and to labor ceaselessly to create machinery with which to kill off or maim those who are spared extinction from disease? To us it does not make sense even in a cockeyed world, much less in a sane one, or does it?

Eighteen Thousand Suicides

Suicide is one of the few crimes, of which we are aware, for which the law punishes failure to commit it successfully It is a major social and medical problem in the United States, according to the Metropolitan Life Insurance Company¹

"More than 18,000 people a year in this country put an end to their own lives, and probably an additional 100,000 make unsuccessful attempts to kill themselves

"It is a melancholy thought," says the *Statistical Bulletin*, "that considerably more than 100,000 people in this country

¹ Statistical Bull. Metropolitan Life Ins. Co 22
-- 5 0 (Mar) 1941

each year find life so hopeless and cheerless that death seems preferable" Under 25 years of age, 1 out of every 6 men, it appears, who attempt to destroy themselves are successful, while at ages 50 and over, the ratio is 2 out of 3. The ratios are different among women. Under 25, only 1 woman succeeds to 18 who fail, but at the age of 50 and over, 1 succeeds to 2 who fail.

The *Bulletin* comments further that the "effort to prevent suicide has hardly been commensurate with the magnitude of the problem." The same *Bulletin*² forecasts for 1941 the prospect of a new health record and a further probable decline in mortality from disease, but "a disturbing increase in motor vehicle fatalities." These, we are informed from

other sources, are said to be, so far, about 12 per cent above those for 1940.

Suicides and motor vehicle fatalities seem to us to be a wastage of life which should not be tolerated with the complacency we seem to exhibit. On the other hand, it seems curiously paradoxical—or something—to attempt to save people from death from these causes only to have them and many others dismembered by bombs, drowned by sinking ships with torpedoes, burned to death by flame throwers, choked by poison gas, shot to death by gunfire, or rolled flat by tanks. There appears to be something a little wrong about our theory and practices somewhere. If we could straighten this out somehow, it might be possible to start a really effective campaign to reduce wastage of life.

A New Test for Pregnancy

Since the introduction of the Aschheim-Zondek test for pregnancy, subsequent work along this line has led to modifications or simplifications of this basic procedure. All of them depend upon the estrogenic substance present during gestation.

Falls, Freda, and Cohen¹ now describe a test which has as its basis the immune and biologic mechanisms responsible for allergic reaction. The material used is colostrum obtained from primipara during the twenty-eighth week of pregnancy. This is diluted with an equal quantity of physiologic saline solution. To 100 cc of this mixture, 0.1 cc of a 1 to 100 dilution merthiolate is added.

This test is performed like all other allergic tests. Using a tuberculin syringe, $\frac{1}{50}$ cc of the above described solution is injected intradermally.

When the patient is pregnant, the resulting wheal will disappear within one hour and the skin surrounding the site of injection will remain unchanged in appearance. In other words, no reaction to the colostrum occurs. In the absence of pregnancy, the wheal increases in size and a pink to red areola accompanies the swelling for a distance of 1 to 2

inches. This flaring is irregular in contour and shows projecting striae. The reaction increases in intensity within an hour of injection and may last for five hours.

Falls and his co-workers performed this test upon 265 cases of definite pregnancy, there were only five false positive reactions in this group. In 113 nonpregnant women wherein this test was employed, four reactions positive for pregnancy appeared. The active protein responsible for this reaction has as yet not been determined.

It seems that the small amount of colostrum appearing after puberty in all nonpregnant women sensitizes the adult body to this protein. The writers feel that a temporary immunity against it is established during pregnancy. The practical application of this test has shown that women on their last day of menstruation will almost always show a positive test. Further experiences will unquestionably produce additional informative observations. Should this test compare favorably in accuracy with those now in general use, it will mean a saving of time and expense. Undoubtedly, the simplicity of this pregnancy test and its ready applicability as an office procedure will bring forth speedy reports of further research.

Cardiac Trauma

One rarely thinks of trauma to the heart without picturing a penetrating wound through its musculature. The spectacular success in the management of cardiac wounds which has been achieved by thoracic surgeons has overshadowed the seriousness of what Beck¹ calls contusion of the heart. These cases most frequently follow automobile accidents wherein the steering wheel suddenly strikes the thorax.

The osseous framework of the thoracic cage possesses a high degree of elasticity. Even when a violent blow has been struck, it may spring back to shape and give no external evidence of injury to the heart. The injured person, after a short period of rest, can usually continue on his way, only to experience later the symptoms of cardiac contusion.

The predominant symptom is a feeling of general weakness, associated with a transient drop in the arterial pressure. Extreme shock, wherein unconsciousness, air hunger, a clammy skin, and an extremely low blood pressure are

evident, speak for severe contusion. Aunclular fibrillation may occur and heart block may result from hemorrhage into the bundle of His. Cardiac contusion should always be suspected when anginal-like pain or epigastric distress and vomiting follow trauma to the thorax. High venous pressure, a low arterial pressure, in the presence of a quiet heart are characteristic of acute cardiac compression. The appearance of deep Q waves, notching of the QRS complex, or inverted T waves in the electrocardiogram will remain permanent findings only if the injury to the heart muscle has resulted in some complete destruction.

In our time, with trauma assuming a more important role in the causation of medical infirmity, the notations of Beck are of the utmost importance. His suggestions for therapy may not meet the exigencies of war, but his recommendations for the use of quinidine, sedatives, and oxygen, among other measures advocated, can be adapted to military use with slight modifications. Contusion of the heart, and its successful treatment, will emerge as another achievement of medicine.

THE IMPORTANCE OF THE INVESTIGATION OF PERSONALITY FACTORS IN PSYCHOSOMATIC PROBLEMS IN MEDICINE

EDWIN J. DORY, M D , New York City

PSYCHOSOMATIC problems in medicine may be divided into three general groups. The first includes those patients in whom a personality disorder resembles, in its symptomatology, a somatic illness. After careful physical studies have excluded organic conditions, the tendency may then be to assume that the patient has a personality disorder. However, the diagnosis of a neurosis or other type of personality disorder is not justifiable on such a by-exclusion basis. Such a diagnosis should depend on the demonstration of definite disturbance in personality functioning.

A second group comprises those patients in whom somatic disease is present but is overlooked because a co-existing personality disorder is more prominent. In these instances thorough somatic studies will reveal these less apparent physical disturbances.

The third group is made up of those patients who show prominent manifestations of somatic illness. These are so apparent that they tend to conceal personality factors that are also contributing to the patients' difficulties. In these cases if the physician is inclined to explain the patients' symptoms as due entirely to the positive physical findings, he will neglect associated important disturbances in personality functioning. To guard against overlooking important personality factors, one should evaluate these factors in all patients having physical illnesses.

Two examples of psychosomatic medical problems will be considered which illustrate the value of an integrated study of physical and personality factors. In the first of these patients the somatic factors might be regarded as predominating over the personality factors, while in the second patient disturbed personality functioning was prominent.

Case Report

The first patient, a 33-year-old, unmarried saleslady, was admitted to a medical service complaining of headaches that had occurred since the age of 7. Until the menarche at 12,

Read at the Annual Meeting of the Medical Society of the State of New York Buffalo, April 29 1941.
Assistant Attending Psychiatrist Payne Whitney Psychiatric Clinic New York Hospital.

From the New York Hospital and the Departments of Medicine and Psychiatry Cornell University Medical College.

the pain had been mild but, since then, had been frequently severe enough to incapacitate her. At times, almost continuous, moderately intense headaches persisted for several days. The pain of a severe throbbing character usually started in the bridge of the nose then spread to the right cheek, orbital region, right side of the neck, and shoulder. These headaches were accompanied occasionally by photophobia, "puffiness" of the eyelids and right side of face, as well as by nausea and vomiting. Mild analgesic or sedative medication afforded only partial relief. A year before admission she was told that her blood pressure was elevated. Shortly thereafter the headaches increased in severity. She also began to have epigastric pain that occurred two or three hours after eating and was relieved by taking milk or sodium bicarbonate.

During childhood her health had been good, and she had adjusted well in her family group and in school. Because of family financial difficulties when she was 14, she had to give up her ambition to become a teacher, leave school, and go to work. For several years she has been a competent saleslady in a large department store. It has been necessary for her to contribute to her parents' support, and she has continued to live in their home.

Because of the nature of her complaints the medical intern, in taking the initial history, investigated her personality organization. It was brought out that she was shy, self-conscious, easily offended, perfectionistic, and serious-minded. She stated that she enjoyed her work and obtained additional satisfaction from attending the theater and concerts, as well as the social gatherings of friends. Seven years earlier, she had contemplated marriage. However, after deciding that the man did not satisfy her criteria of a suitable husband, she decided to remain single. She believed that her subsequent resignation of spinsterhood had been influenced by her knowledge of unhappy marriages in her family.

Among her progenitors, the paternal grandmother and a paternal aunt had suffered from severe headaches. Her father at 61 was high-strung and, because of hypertension, has been unable to work for the past ten years.

Along with this history of the patient's background, the somatic studies revealed generalized excessive perspiration, slightly edematous eyelids, and a blood pressure of 170/100. Urinalysis, kidney function tests, and electrocardiogram were normal. Gastrointestinal x-ray studies showed evidence of duodenal ulcer.

The physician in charge of the patient made the diagnoses of migraine, essential hypertension,

and duodenal ulcer. A soft gastric diet, with medication to reduce gastric acidity, relieved her abdominal distress. The importance of the personality factors, already described in the intern's history, was recognized in formulating the general plan of treatment. Accordingly, psychiatric consultation was requested.

During the psychiatrist's first interview with the patient on the medical ward, she was friendly and pleasant but tense. There was marked flushing of the skin over her neck. She told of becoming "tense, discouraged, nervous, and irritable" when she had a headache and added that the pain was apt to be more severe if she became emotionally upset or fatigued. On being encouraged to discuss her relationships with others she became tearful and evasive. She emphasized her conscientiousness in her work, illustrating this by telling of never going to the employees' rest room to relax. This conduct she contrasted to that of other employees whom she characterized as lazy.

She remained in the hospital for three weeks, and during that time her tenseness gradually decreased. Her pulse rate slowed and was less variable. Her blood pressure varied, the highest reading being 180/120. At the time of discharge it was 150/104. In discussions with the psychiatrist she was encouraged to unburden herself. She was reassured that she could be helped. Particular attention was given to her fear that her headaches were due to a brain tumor. She was given practical advice as to the modification of some of her personality features, especially along the line of securing more relaxation and being less perfectionistic in her attitude toward her work. Various aspects of her family and home situation were considered. The fact that she had been required to subordinate some of her desires to the necessity of contributing to her parents' support was discussed from the standpoint of the significance of frustration and resentment.

Since her return to work it has been apparent that she has gained insight as to the importance of personality factors in relation to her symptoms. Although her headaches have recurred, they have been less frequent and severe. Other than for an occasional dose of mild sedative medication, she has not required somatic treatment. She has been free from abdominal discomfort and quite consistently cheerful. In her work she has been able "to take things more lightly and relax more easily." She has been pleased that this changed attitude has not produced any decrease in her efficiency as measured by the amount of merchandise she has sold. Six weeks after leaving the hospital her blood pressure was 190/95. It has since continued to show a comparable degree of elevation.

Medical literature contains numerous publications that demonstrate the importance of personality factors in the pathologic physi-

ology and clinical course of essential hypertension¹ and peptic ulcer.² Wolff,³ in study of the personality functions of patients suffering from migraine, has demonstrated the importance and therapeutic significance of such features as the perfectionism and emphasis on efficiency which this particular patient showed. In this instance, an awareness of the importance of such factors on the part of the internists studying the patient influenced them to enlist the aid of the psychiatrist in their program of investigation and treatment. The collaboration of the internists and the psychiatrist, although not rendering the patient symptom-free, has succeeded in favorably modifying her complaints. Such treatment has enabled the patient to acquire a helpful understanding of the interplay of various factors that are of importance in the production and accentuation of her symptoms. This understanding has aided her in the working out of modifications of her personality reactions which should benefit her not only in the way of diminishing her complaints but in achieving a more satisfactory life adjustment.

The second case to be considered presents a different type of psychosomatic problem. Here, the manifestations of disturbed personality functioning were outstanding and brought about the patient's admission to a psychiatric hospital. Evidence of hyperthyroidism was also recognized. This constituted an important somatic factor that could not be neglected in any broadly inclusive and well-integrated formulation of study and treatment.

Case Report

An 18-year-old, unmarried youth was admitted to a psychiatric inpatient service because he had displayed emotional instability and poor judgment. A short time before, he had done so poorly in the final examinations of the first semester of his freshman year that he had been asked to leave college. During the preceding three months he had been restless and tense and had shown a marked tremor of his hands. He had lost 21 pounds in weight and smoked excessively. Although previously temperate, during this period he had used alcoholic beverages almost daily and occasionally in excessive amounts. While taking his final examinations, he was troubled by the local discomfort caused by pediculosis pubis. Although he had not had sexual contact, he was concerned greatly as to the significance of this condition. This reaction seemed to be related to the fact that in a recent hygiene course he had been much impressed by pictures that depicted the effects of syphilis.

Shortly after leaving college, he wrote several

checks that represented a sum of money considerably greater than the amount he had on deposit in the bank. He did this to make part payments for an automobile, two radios, and considerable clothing. His parents, having been informed of his behavior, asked him to return home. He complied willingly but refused to discuss his injudicious purchases, attempted to buy another automobile, and continued to display restlessness and tremulousness. The private physician's clinical studies revealed excessive perspiration, tachycardia, and a basal metabolic rate of +31 per cent. This physician, also being impressed by the patient's emotional instability, excessive use of alcohol, and poor judgment in the use of money as evidences of disturbed personality functioning, advised that he be admitted to a psychiatric hospital.

The patient was the only child of parents in modest circumstances. Other than for some occurrence of nail-biting in childhood, his developmental history revealed nothing unusual. His health had been good, and he had made a satisfactory scholastic record in grammar and high schools. The study of his personality represented him as an active, energetic, even-tempered, outgoing, sociable youth with a fairly wide range of interests. In his associations with those of his own and the opposite sex, he had appeared to adjust well. He was fond of his parents and demonstrative of affection. In his attitude toward himself he had displayed a desire to be neat and well dressed. He had shown a tendency to act impulsively on judgments. His parents thought that he had felt a lack of money while at college where, for the first time, he was associating with others of his age group who were members of wealthy families. He had never indulged in sexual intercourse, feeling that this was not desirable until after marriage. There was some evidence that the expression of a contrary code of sexual morality by some of his reputedly more sophisticated college associates had engendered in him some conflict and uncertainty. He denied experiencing any concern over his occasional practice of masturbation.

In his hereditary background, a paternal uncle was noted to be moody. Also a female paternal second cousin at the age of 38 had a depressive illness complicated by hyperthyroidism. She died of exhaustion and cardiac failure a few days after admission to a hospital for mental illness. Apparently the patient had not been upset by the psychopathologic disturbances displayed by these two relatives with whom he had come in contact only occasionally.

On admission, he was friendly but facetious, boastful, and self-satisfied. He minimized his recent difficulties and rationalized his unusual behavior. He made a fairly good adjustment to the hospital routine but desired participation in much more strenuous physical activity than he was allowed. Tests of orientation, memory, and the retention of immediate impressions were

well performed. A psychometric examination indicated that he was intellectually capable of doing college work.

He was well developed physically but appeared to be somewhat undernourished. The thyroid gland was moderately and diffusely enlarged. There was a coarse tremor of the extended hands and slight impairment of ocular convergence. Tendon reflexes were slightly hyperactive, and his hands and feet perspired excessively. The heart was not enlarged. His pulse rate varied between 86 and 108 per minute, his blood pressure was 140/55. The creatine tolerance test showed normal retention. Basal metabolic rate was +50 per cent.

The diagnostic opinion of the hospital staff was a mild hypomanic excitement with hyperthyroidism occurring in the setting of late adolescence.

During the first two weeks in the hospital he lost weight, although he ate well. Thereafter, he gained weight progressively. An internist saw him in consultation and confirmed the diagnosis of hyperthyroidism. On that physician's advice the patient received syrup of hydriodic acid 4 cc daily, luminal 0.030 Gm three times a day, calcium lactate 0.6 Gm three times a day, and a high-vitamin diet. In addition, his physical activity was limited, and he received a sedative bath of one hour's duration each afternoon. On this regimen his pulse rate slowed, the tremor of his hands decreased, and he slept well. Two weeks after admission his basal metabolic rate was +47 per cent. This then decreased progressively, and at the end of four weeks in the hospital it was +17 per cent. The luminal and the sedative baths were discontinued six weeks after admission, and he was permitted to increase his physical activity gradually. Occasional brief periods of mild depression and tearfulness occurred. The boisterousness and resentment of supervision diminished gradually and disappeared after about eight weeks of hospital residence. At that time he began to make visits accompanied by his parents.

During interviews with the psychiatrist, the patient discussed his behavior before admission and gained some insight as to the significance of his excessive use of alcohol and his poor judgment. Various aspects of his personality functioning were discussed with him, such as the conflicts arising from the interaction between his instinctual urges and the restraining influences of his ethical standards. Attention was also given to the difficulties he had experienced in his social and academic adjustment in college. There, the environmental demands were of a different type than those presented by his modest home circumstances and the less exacting educational requirements of a small high school. His tendency to resent supervision and to display boastfulness and irritability were analyzed with him in terms of the particular significance of the personality problems of adolescence.

and duodenal ulcer. A soft gastric diet, with medication to reduce gastric acidity, relieved her abdominal distress. The importance of the personality factors, already described in the intern's history, was recognized in formulating the general plan of treatment. Accordingly, psychiatric consultation was requested.

During the psychiatrist's first interview with the patient on the medical ward, she was friendly and pleasant but tense. There was marked flushing of the skin over her neck. She told of becoming "tense, discouraged, nervous, and irritable" when she had a headache and added that the pain was apt to be more severe if she became emotionally upset or fatigued. On being encouraged to discuss her relationships with others she became tearful and evasive. Although he had not had sexual contact, he was concerned greatly as to the significance of this condition. This reaction seemed to be related to the fact that in a recent hygiene course he had been much impressed by pictures that depicted the effects of syphilis.

Shortly after leaving college, he wrote several

PRACTICAL ASPECTS OF PSYCHIATRIC MANAGEMENT IN PSYCHOSOMATIC PROBLEMS

GEORGE E. DANIELS, M D, New York City

THE growing interest in psychosomatic problems raises the natural question in the minds of the general medical man "What should I do about it?" Overselling of the emotional factors in disease—even emphasis on them—without indicating at the same time the avenue of effective discharge, is poor mental hygiene and can only lead to a feeling of frustration and actual delay in progress in this field because of premature enthusiasm without opportunity for adequate action.

It is my intention in this communication to indicate a few of the practical aspects of the treatment of psychosomatic cases in terms that will be understandable and useful to the man in general medicine or in specialties other than psychiatry. I hope you will not be disappointed because the paper does not deal with indications and dosage of medication, supportive treatment in toxic cases, or criteria for hospitalization. These are intensely practical problems but have been dealt with elsewhere, whereas the equally important questions of judgment on how far to go in preliminary psychotherapy or in the management of the emotional problem have been inadequately discussed as far as the general practitioner is concerned.

"Should the general medical man do psychotherapy?" This question, often heard, is improperly phrased. The family doctor, in fact any doctor who cares for a patient over any period of time, cannot avoid exercising a psychotherapeutic influence, either positive or negative. The question is, rather "To what degree can the doctor make his general medical treatment more psychotherapeutically effective, and to what degree, if any, should he utilize psychiatric technique?"

One often hears it said that the theories and practices of the psychotherapist appear fantastic and that all that is necessary in handling personality problems is common sense. A good seasoning of common sense is valuable in any relationship, but it is an error to think that without knowledge of psychodynamics one is in a position to manage or

treat neuroses. The obvious surface phenomenon often belies the deeper trend and, unless one knows how to reduce both to a common denominator, pure application of common sense may produce far from the desired result.

The situation presented by the emotional complications of physical disease, be the symptoms predominantly physical or functional, calls for a mixture of boldness tempered by caution in the initial handling. Not to go far enough is to deprive the patient of the security of his illness without pointing the way out. To go too far, especially if this is done precipitately, may plunge the patient into a much more serious mental disorder or bring about a marked accentuation of the physical symptoms. As in any branch of medicine, the kind and degree of treatment depend on the selection of the case and the training and experience of the physician. I should like to use one of the most frequently encountered symptom complexes to illustrate approach and handling. The same general principles hold for psychosomatic symptoms encountered elsewhere in the body.

A patient comes to the hospital or office complaining of cardiac symptoms. These may be mild, in the form of occasional palpitation and precordial discomfort, may consist of tachycardia with some extra systoles, or may be in the nature of full-blown attacks, with palpitation, sweating, and a choking feeling with difficulty in breathing. Accompanying such attacks, which may last fifteen or twenty minutes, there may be great apprehension and fear of dying. The patient, whatever the degree of the symptoms, fears organic heart disease and either comes, or is brought, for examination.

The history and a careful physical examination reveal no evidence of serious physical disorder. We will assume that the physician knows his physical diagnosis and recognizes the condition as functional. He may go so far as to recognize it as the clinical picture of anxiety. What is his next move? There is no question that, in cases in which no structural disease is present, reassuring and convincing the patient that he does not have a serious or fatal malady is an obvious and necessary step in the therapeutic procedure. The time and way this is done, however, may

Read at the Annual Meeting of the Medical Society of the State of New York, April 29, 1941, Buffalo, New York.
Clinical professor of psychiatry, Columbia University.

From the Departments of Psychiatry and Medicine, Columbia University.

As the evidences of hyperthyroidism persisted, the internist in subsequent consultations raised the question of the advisability of thyroidectomy. He did this because he thought the hyperthyroidism might have deleterious effects on the patient's cardiovascular system and that such changes might persist. However, electrocardiographic and x-ray studies of the heart during the tenth week of hospital residence showed no variation from normal. At that time the patient was becoming more stable emotionally and was making a good social adjustment. His pulse rate was becoming stabilized at a lower average level and his basal metabolic rate was +6 per cent. It appeared that, along with his improvement from the psychiatric standpoint, the hyperthyroidism was diminishing. Accordingly, it was decided that the continued medical treatment of the thyroid dysfunction was justifiable.

Fifteen and one-half weeks after admission the patient was discharged to return home. He had gained 14 pounds in weight during his hospital residence, and his basal metabolic rate was +3 per cent. Also, the thyroid gland had decreased in size. He was instructed as to a routine of gradually increased physical activity and was advised to continue taking a daily 4-cc dose of syrup of hydriodic acid. On the advice of his private physician it was later discontinued.

Sixteen weeks after leaving the hospital his basal metabolic rate was -1 per cent. After several months of business training, he secured employment in the accounting department of a large manufacturing corporation, where he is doing satisfactory work. He expresses himself as pleased with his situation. During his last visit home, three years after the onset of his illness, his parents noted no evidence of his former symptoms and regarded him as stable and well adjusted.

The relation of hyperthyroidism to personality disorder is a complicated one, both etiologically and symptomatically. The thyroid dysfunction, in some instances, appears to be the cause of the personality disorder. In other patients it seems to be rather an effect of the mental abnormality. In this case the history presents the manifestations of hyperthyroidism as appearing before the symptoms of the hypomanic reaction. This suggests that the personality disorder might have been secondary to the hyperthyroidism. Rather than enter into a discussion of such possible etiologic relationships, it is more pertinent to the purpose of this communication to emphasize another aspect of this clinical problem. That is, the importance of recognizing that in this case one was dealing with the interplay of two types of illnesses and should, therefore, try to avoid attributing all the symptoms to one or to the other of the two

Many discussions of psychosomatic medical problems place much emphasis on the physician's being aware of psychologic factors in his patients. The second case presented demonstrates another aspect of the study of psychosomatic problems which has not been stressed to so great an extent. The reference here is to the fact that it is essential for the psychiatrist to possess an adequate knowledge of the problems of physical illness. He will then be less likely to overlook somatic factors in his patients while he focuses attention on disturbances in their personality functioning. Also, in consultations with his medical and surgical colleagues, he will be able to make more helpful diagnostic and therapeutic contributions.

There is a general acceptance of the belief that personality factors are frequently of importance in various somatic illnesses. In closing, I should like to call attention to some studies that substantiate this concept. Dunbar⁴ and her associates, during a two-year period, studied all patients admitted to the Presbyterian Hospital in New York City for the treatment of cardiovascular disease, diabetes, or fractures. In 300 out of the total 605 patients studied, a detailed psychiatric investigation could be conducted. It was found that emotional factors played a role in more than three-quarters (78.67 per cent) of these 300 patients. Ripley,⁵ in a review of his work as the psychiatric consultant to the New York Hospital, reported on 218 patients whom he studied during one year. This group represented 15 per cent of the total number of patients admitted to the medical service during that period. In approximately one-third (32 per cent) of these cases, physical illness was complicated by psychoneurotic features. Only 4 per cent of the entire group showed no positive psychiatric findings contributing to the diagnostic formulation.

It is to be hoped that, with increasing familiarity with the importance of psychologic factors in the problems of illness, physicians will use the investigation of personality functions as an integral part of their studies of patients.

her voice while telephoning home. No local pathology accounted for this. The suspicion that there was a large hysterical element, coupled with her failure to act favorably to reassurance that her heart was sound, led to psychiatric consultation and treatment.

A careful recheck of the circumstances surrounding the onset of symptoms revealed that her first attack of palpitation had occurred on the evening of the graduation from high school of a daughter who had recently become engaged and three days after the marriage of her only son, who was 21. This son's announcement that he was going to marry had been a great shock to her and, although his fiancée was perfectly acceptable, the patient opposed the marriage on the grounds of his age. She openly showed her resentment that anyone should replace her in his affections and claimed that she had not known they were keeping company, although the son had made no secret of it. In spite of her objections he had gone ahead and married. On top of the physiologic evidence that one chapter of her life was closed, the patient's children were leaving her, preferring others to her and flouting her authority. Under such circumstances there was a last desperate effort to hold attention and affection through illness, utilizing autonomic phenomena undoubtedly made available by the climacteric.

In this case, medical opinion had tended to reinforce into a conviction the patient's own fear that she had serious heart disease. The local physician who was called at her first attack of palpitation told her that she had heart trouble and prescribed digitalis. The shock of this information led to her fainting. She went to bed for a week and for the next three months suffered from attacks of dizziness and weakness. And then, when the son and his bride moved from the patient's home, her severe heart attacks began. During the next five years she saw many doctors who made diagnoses of heart trouble, menopause, and diabetes. One doctor said she would not live long, and after this information her attacks became more severe. The fact that the menopause and, later, the mild glycosuria gave some physical basis for her symptoms had blocked inquiry into the emotional factors.

The patient's aphonia had first appeared after her husband had given up sexual relations with her because of his fear that it would be injurious to her health. The couple had been given no advice on this, an improvement occurred later when relations were re-established.

We have no time to go into the question of the diabetes which, although in this case it is perhaps adequately explained by the menopause, often has important emotional components. Earlier attention to these emotional components might have postponed, if not prevented, the diabetes, although at the present state of our knowledge this is conjecture.¹

The emotional reasons for this patient's dis-

turbance were uncovered and dealt with by showing her that she was passing through what every woman must experience, and by showing her that neither this nor the fact that her children would inevitably grow up and marry if they were healthily independent was worth chronic invalidism and the eschewing of satisfactions still open to her. At the same time the house physician patiently repeated his examination of her heart from time to time in order to reassure her more forcibly, and the nurses who took special pains to increase the range of her activities were instructed to use reassurance generously. By dint of this combined therapeutic approach, the patient, who had been confined to her house for two years—most of which time was spent in bed fearing the worst—got about sufficiently to be discharged after a month, and she returned regularly for outpatient medical and psychiatric treatment. Although she continued to have some attacks, they did not materially limit her activities. She resumed visiting her friends, going to the theater, and doing light housekeeping during the next few years, with occasional visits to the psychiatric clinic for relatively superficial psychotherapy.

The taking of additional history that contains the elements of the emotional conflict, as in the foregoing case, may represent a psychotherapeutic act in itself. When this is directed to bringing about emotional discharge of affect, it is called mental catharsis. This is simply a more technical term for getting the patient to unburden to the physician—a therapeutic maneuver that the priest and wise physician have been aware of from time immemorial.

Every intuitive person knows how much relief a good cry may give in a situation of grief or how expressing one's anger to a second person will bring it into control or leave one better poised to do battle. These truths, however, are often lost sight of in the pressure of medical practice and on a busy hospital ward. They are often considered detrimental if the patient has some incapacitating physical disease. "Don't cry, it simply upsets you," is a frequent admonition. In the general hospital it is commonplace for the ward personnel and patients to become adjusted to a patient's cries or moans as an expression of physical pain, but, if the pain is mental, there may be little patience or understanding. Naturally, one cannot allow a general medical or surgical ward to become a psychopathic one, but the suppression of quiet crying often defeats its end and, if psychotherapy of any depth is to go on, one would expect some emotional cathartic relief to occur. This is especially so when it is working

be signal in the entire management of the case

In milder cases the reassurance that there is no serious physical disease may lead to prompt relief, and in the mildest cases, particularly in adolescence, such reassurance may be sufficient to tide over the situation, and it may be unnecessary to go further into the matter. However, if the underlying conflict is severe, the effect of reassurance cannot be more than transient, and perhaps it should be temporarily withheld until one has had an opportunity to take further bearings on the case.

The circumstances under which information—even obvious information—is conveyed to the patient must take into account the seriousness of the neurosis and the extent to which seemingly unsolvable environmental factors lie behind the symptoms. To tell a patient who has been suffering from severe functional cardiac symptoms for several years that there is no trouble with his heart, without further preparation, may be fraught with serious consequences—sometimes even with the precipitation of a psychosis. A patient whose serious maladjustment has been screened behind physical symptoms cannot tolerate a too rapid tearing away of the mask that has been afforded to his most intimate struggles—a mask also acting as a screen even to his own conscious appreciation. The result may be no change at the time, the symptom may disappear to reappear shortly in some other organ or the patient may seek refuge in a psychosis. I recall one such patient who had been sitting on a volcanic marital situation for ten years. Her main safety valve had been attacks of palpitation. These erupted into a hysterical stupor and approached a catatonic episode when it was explained to her that she did not have heart trouble. Her main problem was too abruptly approached. In psychosomatic medicine, as in surgery, there are certain walled-off diseases that should be opened up only, if at all, under the most scrupulous application of technique.

If the manifestations are not sufficiently mild to justify the physician's strongly reassuring the patient with the prospect that this alone will be sufficient, what is the next step in procedure? This must be in the form of a cautious investigation into the sources of conflict, so that the patient's attention may gradually be directed toward the seat of the difficulty. Whether the general medical man or other specialist is able to deal with the problem, or whether it needs to be handled by a

psychiatrist, depends upon the depth and seriousness of the difficulty and upon the physician's understanding of mental phenomena. Simply to reiterate to the patient that there is nothing the matter with his heart, or to go even further and insist that the difficulty is simply imaginary, is likely to lead to confusion or vehement disbelief or anger, if not to the other contingencies mentioned. The patient knows that he has the symptoms, and as the symptom is based on disordered function—though from a different source than that of organic heart disease—it cannot be relieved until one deals with the more fundamental situation.

In attacks of neurotic anxiety expressing themselves through heart symptoms, it is important for the practitioner to bear in mind that these symptoms may arise in one of a couple who are using biologically unhygienic methods of contraception or who are ignorant about the mechanics of intercourse. In a few instances, proper contraceptive advice or simple sexual instruction may bring brilliant results. Such uncomplicated cases are not common and, if the symptoms are severe, usually a more deeply seated neurosis is present.

The following case represents an example of a patient who had become a chronic invalid through mismanagement but who was considerably helped by the utilization of a pertinent psychiatric history in conjunction with repeated reassurance and medical re-education.

Case Report

B R, a Jewish housewife aged 53, was admitted to the Presbyterian Hospital for heart trouble of five years' duration, mild diabetes for three years, and attacks of hoarseness for two years. The onset of her illness occurred a few months after the first signs of the menopause. Her attacks consisted of precordial pain, palpitation, and irregular breathing with extra systoles and prolonged compensatory pauses. The patient was convinced that she might die during an attack. The attacks were precipitated in the hospital whenever she attempted to exert herself and often were accompanied by hoarseness, although this symptom also occurred independently.

Careful physical examination revealed no organic cardiovascular disease. Her periods still occurred irregularly. She had a mildly elevated blood sugar level, which was controlled by diet. It was noted that she was apt to have her most severe attacks during visits of the family when she would often lose her voice completely in their presence but recover it rather promptly after their departure. On one occasion she suddenly lost

also mentioned that since her outburst toward her mother-in-law she had "put the whole thing out of her mind." The probable relationship between the two phenomena, accentuated pain and successful forgetting, was pointed out to her. She reported during the following interview that the pain in the breast had subsided the day of the last visit, that she had begun to sleep regularly, and that she felt better than she had for a long time. The conflict over the mother-in-law had been brought to the surface to be discharged through normal channels and was in the process of being successfully worked through.

The preceding example illustrates the fact that the material that may come out during mental catharsis may have a considerable weight of hostility behind it. In this instance, its very emergence in the medical situation made it possible for the patient to clear the atmosphere in the environmental situation. It is also important to bear in mind that, in the process of releasing underlying hostility, this may turn temporarily onto the physician in the course of the therapeutic situation. If the physician does not recognize this, he may mistake it for a sign of uncooperativeness and refuse to have further to do with the case, instead of dealing with it as a step in the therapeutic procedure.

The problem of when to give advice in cases with psychosomatic complications is important. In general, one seeks—as in the last case—to let the patient work out his own problems with the sympathetic and understanding attitude of the physician being maintained without injecting himself too much into the picture. It is bad psychotherapy, for example, to recommend that a middle-aged spinster get married when there is little opportunity of fulfilling this, that a neurotic woman have a child when there are strong resistances against it, or that a couple get divorced—even though the physician has recognized that the symptoms show conflict regarding these problems. If the obstacles, either neurotic or actual, are removed, the patient will proceed to the healthy solution of his problems. But if the obstacles have not been removed, advice—especially if accompanied by pressure—will only increase the complications.

The following case illustrates the situation in which the patient's own insight was reinforced by recommendation and encouragement from the physician. In order to become effective, however, this had to be distributed over a period of years, during which care had to be exercised that the patient was not pushed beyond her capacity to respond.

Case Report

M B., a single mulatto aged 29, was followed for eight years. During this time she had five attacks of severe ulcerative colitis, several of which necessitated months in the hospital. At the time of her first hospitalization during her third attack, she reported that she had been attempting for several years to leave her sister and sister's child who made undue financial and other demands upon her. She was on the point of transferring to a branch of her firm in Hollywood when the attack occurred. She remarked "I guess the excitement was too much." When she recovered from this attack she was given encouragement to make another attempt, but each time she made a move in this direction she would have a recurrence, or near recurrence. One such attack, for example, occurred when she had gone so far as to pick out another apartment away from her sister but in the same city. Finally, she did make this change. Then an open break with her sister followed, during which the patient was able to express openly her resentment. After a few months she made her long-delayed move to California. From there she reported that she was happy and contented and free from physical symptoms. In this case the total amount of time spent in psychotherapy was not great, not more than a man in general practice could have given. The indicated recommendation was clear, but judgment was necessary in the pressure with which this recommendation was followed up.

It is not the intention to imply that serious cases of ulcerative colitis can be cured by such a procedure alone. This patient had careful medical care during attacks. The condition is known to show remissions, and there is a question whether patients who have had severe attacks of ulcerative colitis ever entirely recover because of irreversible changes in the colon.

This problem is too complicated to discuss in detail at this time, but it is worth emphasizing that many cases of ulcerative colitis show clear-cut relationships to emotional difficulties, and, in many instances, improvement of the condition goes hand in hand with the resolution of the conflict. At the Presbyterian Hospital we have been particularly interested in following such cases. Dr Langford, at the Babies Hospital, reports that cases in which the psychiatric aspects have been followed do consistently better than those in which this has been neglected.² Sullivan³ reported favorable results from an experiment in psychotherapy on the wards of the New Haven Hospital. The more detailed treatment of one of our own series has been recently reported.⁴

its way out gradually and with no special effort to evoke it

To tell a patient that he cannot do anything about his troubles and, therefore, to forget them can have unexpected reverberations. One such case was that of a 17-year-old girl with rheumatic heart disease who was given such advice on the ward when she showed grief in a perfectly normal way after a close friend, another patient on the ward, had died. The admonition to forget it was only too successful. The succeeding days she became calm and placid, but the following night she began a series of sleepwalking episodes which were ever so much greater strain on her heart than her quiet crying would have been. Of course, this is not a usual case, and a somnambulistic background made it possible to show such far-reaching effects, but it illustrates the danger of too vigorous repression of affect.

In extremely neurotic individuals, however, such unburdening cannot be encouraged with impunity. Under certain circumstances it even should be discouraged unless one has the time and necessary skill to go into a prolonged and carefully controlled analysis. The physician may unwittingly, because of a desire to be sympathetic, have the whole neurosis plopped into his lap without knowing what to do with it. The result may be a hopeless emotional tangle, and the last state of the patient may be worse than the first. One does not cure cancer by sticking a knife into the center of the diseased process. I believe that one of the reasons some physicians seem lacking in understanding when dealing with neurosis is an intuitive protection against such a situation arising. The danger would not be any greater, however, and the patient in the end might be the gainer, if such intuition were replaced by conscious awareness.

I have emphasized the importance of letting natural feelings express themselves, and I have stressed the danger of opening up the more serious emotional problems without time and professional training to deal with them. What should the physician's criterion be for encouraging the patient to unburden? It should be the same as that used in determining whether to give the patient insight into the emotional sources of his illness, which has been outlined above, i.e., the extent of the neurotic process and the severity of the environmental threat. If either or both of these show malignant ramifications, it should not be attempted by any but an expert. However, when the disturbing situation expressing

itself in a symptom is rather discreet and the rest of the environment will not tumble about the patient's head if he reacts appropriately, it is important for the practitioner to lend his aid as a sympathetic listener, perhaps confessor.

I should like to cite an example of a case that was treated by a third-year medical student, under supervision, in the psychiatric clinic to illustrate the successful operation of an emotional cathartic process.

Case Report

O C, a married woman aged 30, was referred from the Surgical Clinic where she had been under treatment for a month for chronic mastitis. Three weeks before coming to the clinic she had developed a lump in one breast, which she attributed to a blow, but she had been having some discharge from both breasts since weaning her 2-year-old child at eleven weeks. She was referred to psychiatry for insomnia, which first appeared after the birth of the child. It was noted that the affect connected with her complaint of pain in the abscessed breast was more than was to be expected and seemed to be psychoneurotically overdetermined.

After being followed for three weeks she came in one day, told the medical student that there was something that she had not spoken of because it was so personal, and launched into a tirade against her mother-in-law. This woman, she stated, had tried to interfere with the marriage to her son, was strenuously opposed to their having a child, and suggested when the patient was several months' pregnant that she have an abortion. When the child was born, however, the mother-in-law attempted to take over the whole management of its care and went to the patient's house several times a week to supervise her activities and to criticize. Though the patient's husband sympathized with his wife and though she was "burning up inside," her normal reticence had prevented her from defending herself. She stated that she had come to the conclusion shortly after starting the psychiatric interviews that this situation was the cause of the insomnia as well as of some of her other troubles. She had decided to break off gradually with her in-laws, and she had been sleeping and feeling better since she made this decision. In giving the account, her eyes flashed and she showed a tremendous accumulation of feeling and resentment.

The patient left the clinic, and shortly after arriving home her mother-in-law called her on the telephone to nag her about giving the baby bacon to eat. The patient promptly unloaded on her tormentor all the accumulated venom of the preceding four years. This was her first attempt to strike back. During the succeeding three weeks the pain in the breast was much accentuated. When reporting this in clinic she

THE TREATMENT OF FAVUS OF THE SCALP

GEORGE M. MACKEE, M D , GEORGE M. LEWIS, M D , and MARY E. HOPPER, M S ,
New York City

THE symptoms of favus are frequently slight and progression of the disease is often slow. Most of the cases we observe give a duration for the disease of several years. There is considerable variability in the degree of severity of sequelae. The disease may be present for many years and yet, when it is treated and the infection eradicated, little permanent alopecia will be noted. In other cases permanent alopecia may occur even after a few months. If treatment is adequate and carried out with thought to the findings of the individual patient, the ultimate result is usually satisfactory provided atrophy has not previously supervened. Favus is usually contracted in childhood and most of our adult patients acquired the disease before puberty. Women are more often infected than men. Due to the length of their hair it is easier for women to hide the disease.

Patients are usually advised by their physicians that the disease is difficult to eradicate and that x-ray epilation (which may be difficult to obtain) is essential to effect a cure. Most patients with favus are not well educated and usually have the impression that they are harboring a shameful disease. These factors tend to bring about an unfortunate attitude of defeatism and, together with the insidious nature of the disease, contribute to neglect in instituting treatment.

Our experience would indicate that favus of the scalp is not more difficult to cure than many other forms of *tinea capitis*. The slow progression of the disease and the fact that the infected hairs are usually less weakened by the invasion of *Achorion schoenleini* than with many other fungi make favus of the scalp frequently more tractable than infections such as those due to *Microsporon audouinii* or to *Trichophyton violaceum*.

The management of the patient with favus appears to be imperfectly understood. In most texts on dermatology the fundamental procedures are given but the details essential to cure are not completely outlined. It is important to study each patient as an individual problem. During the preliminary period of examination the patient should be examined

for other foci on the skin or in the nails. Once the disease is recognized, the further management of the patient may be considered under the headings of "Case-Finding" and "Eradication of the Disease."

Case-Finding

An effort should be made to trace the source of the infection and to examine the contacts of the patient, particularly children in the immediate family. The following case illustrates the value of careful study of both the patient for concomitant lesions and of the family for other infections.

Case Reports

Case 1—F B, a housewife aged 27, was born in the United States of Italian parents. She first developed a crusted condition of the scalp twenty years before. This had gradually spread over the scalp to include all areas except over the occiput. She had not previously sought advice from a physician. Examination disclosed a widespread crusting of the scalp, forming an almost solid lamellated matt (Fig 1A). There was an offensive, pungent, musty odor, which soon fouled the air in all parts of the examining room. Many apparently normal hairs were present on the infected parts of the scalp, piercing the crusts and obscuring the extent of the disease. When some of the crusts were lifted off a livid red bleeding surface was exposed. Under the filtered ultraviolet rays, fluorescent hairs were seen to be distributed throughout the involved areas. The direct examination of a potassium hydroxide preparation revealed an endothrix infection with irregular filaments and spores and air bubbles typical of *A. schoenleini*. The cultural growth later confirmed the diagnosis of favus. There were also crusted lesions with involvement of hairs on both legs, discovered after a careful inspection of the skin and nails.

Investigation of the relatives revealed the following:

(1) The husband of F B showed no evidence of the disease. They had been married for ten years. Of their 4 children, 3 showed clinical evidence of favus of the scalp, later confirmed by culture. The children who showed the infection were a girl aged 8, a boy aged 5, and a girl aged 14 months. A girl aged 3 showed no infection. In all cases the scalp alone was affected.

(2) M M, a married sister aged 23, had a diseased scalp for about the same period of time (twenty years). Examination disclosed an in-

From the Skin and Cancer Unit, New York Post-Graduate Medical School and Hospital, Columbia University.

Summary

I have attempted in this paper to outline a few of the practical problems of management in general medical situations in which psychiatric insight is essential. These consisted in the use made of a negative physical examination for reassurance of the patient, the necessity of evaluating the point at which insight should be given into the emotional component of a psychosomatic disorder, the exercise of judgment in encouraging the patient to unburden and its relation to the use of mental catharsis, and, last of all, the question of giving advice

to patients with personality disabilities. The field of psychotherapy in psychosomatic disorders is not only vast but in large areas is uncharted. I have tried to pick out a few principles that are well established by experience, and I hope those chosen will prove of help in routine management of such cases.

THE PSYCHOLOGY OF QUILSLINGISM

Most of us have been surprised by the influence that Hitler has exerted not only over his own people but over individuals in countries not his own—those who have been willing to collaborate with the Nazis even at the expense of their compatriots. The outstanding, and to ordinary eyes despicable, Quisling phenomenon is open to a variety of explanations—"Every man has his price," and "Nothing succeeds like success." There is, too, the stuff of which revolutionaries are sometimes made, such as spite, injured pride, bitter feelings of inferiority, and sensations of frustration and impotence in the face of the prevailing order. No doubt many of Hitler's converts are psychopaths like Hitler himself, but without the energy which makes him look like a genius. They are, in fact, in Henderson's terminology, "aggressive" but not "creative" psychopaths. Although these explanations are satisfactory up to a point, the suspicion that they do not explain everything is shown in the frequent references to the so-called hypnotic powers of Hitler, not only over his own people but over his political visitors. It is recorded of Napoleon that he had a similar effect in engendering fanatical and childlike self-abnegation in some people. Tolstoy, with the intuitive veracity of the first-class novelist, records in *War and Peace*, how an elderly warrior, his face flushed and his eyes gleaming, led his troop through a river, drowning forty of them in the process, for no better reason than that Napoleon was looking on. "Quos Deus vult perdere, prius dementat." There is no sense in such a performance, it is rather a kind of masochism. Those who to this day collect relics of Napoleon, and in a sense worship his memory, are examples in vitro of the same

kind of abasement. Devotion of such sort deserves examination for its unconscious roots. Dr. Ernest Jones, in a recent analysis of the psychology of Quislingism, has described the various attitudes of those who approved of Nazism—the passive acceptance of the slum-dweller, who thought it a matter of indifference who governed, the denial of Hitler's aggressiveness by the escapist, who asserted there would be no war, the partial admission of Hitler's aggressiveness by the appeaser, who thought it could be bought off, and the man who thought the aggressiveness quite justifiable and even advisable. Jones ascribes all these attitudes in their various degrees up to the fully developed acquiescence and cooperation of the Quisling to the unconscious attitude toward the father. There is fear of him, and of one's own dangerous impulses toward him. The Quisling way is to identify might with right, and to say that because these dangerous impulses are strong they must also be good. At the same time they are denied within the subject himself and projected on to the father, who thereby becomes good as well as powerful and with whom the potential Quisling identifies himself. The attitude is psychologically homosexual. However hypothetical these speculations may be, they emphasize what is clearly important—namely, the part played by guilty feelings in inhibiting resistance to Hitler. German propaganda has in this respect taken a leaf out of the book of some religions. It has known too well how to play on the existence of a sense of sin in the people of the Western civilization—a sense which Freudians believe to be based on the forgotten unconscious conflicts of infancy and childhood.

children would have been recognized and treatment instituted for several months or years. Since favus chiefly affects people in an uneducated stratum of society, one cannot trust the history of lack of infection in other members of the family. It is best to examine personally the intimate contacts of the patient

Eradication of the Disease

The keynote to treatment of a patient with favus is epilation of the infected hair. We know of no medicinal preparation (fungicide) that is curative without the concomitant use of depilatory measures. Active treatment may be discussed under the following Preliminary Local Applications, Epilating Measures, and Aftercare When X-Rays Are Used.

Preliminary Local Applications—While the disease as it affects the scalp is fundamentally a follicular infection (with invasion of the hair shaft), the microorganism also proliferates on the surface of the scalp to produce a thick crust. Before any depilatory procedure is instituted it is advisable to remove all crusts and reduce the amount of inflammation of the scalp to a minimum. Besides ridding the scalp of a nidus of infection, which may reinfect other hair follicles, it is important to clean the scalp, to reduce severe inflammation, in the presence of which it is inadvisable to use x-rays, and to eliminate thick crusts that would tend to filter out some of the rays and reduce their effect. Manual removal of the crusts by forceps may be accomplished after they have been softened with a bland oil. The same result may sometimes be obtained, if the crusts are not too thick or too extensive, by the use twice daily of an ointment containing 4 per cent each of salicylic acid and sulfur precipitate and by washing the scalp thoroughly with soap and water at intervals of two or three days. The average time required for the preliminary local treatment is three weeks.

Epilating Measures—Some form of epilating treatment is requisite in the treatment of favus of the scalp. If the disease is limited in extent, hand epilation using a blunt forceps, with selection of diseased hair made certain by carrying out the procedure under filtered ultraviolet rays, is adequate and preferable to the use of x-rays. X-ray epilation is indicated in cases where the disease is widespread over the scalp. Such therapy must be carried out with due caution, and to obtain good results the machine must be accurately calibrated and the operator of the machine must be well trained.¹ The following 2 cases

illustrate the clinical type in which manual epilation may be used with success.

Case Reports

Case 2—N. A., a white woman aged 21, was born in Arabia and had been in this country for the past two years. The disease had been contracted ten years before. Examination disclosed irregular, dollar-sized patches on either parietal region with a few other lesions scattered over the scalp. There was considerable atrophy and moderate crusting, and fluorescent hairs in the patches were observed in filtered ultraviolet rays. The diagnosis of favus was verified by culture. The application for six weeks of an ointment containing salicylic acid and sulfur precipitate resulted in the disappearance of all crusts. She reported to the clinic once a month for four months at which times manual epilation was carried out. A month later only one infected hair was present, and in two months there was no evidence of any infection. During the course of treatment the normal hair was left uncut and, although this increased the difficulty of finding some of the infected hairs, it was nevertheless possible to effect a cure. It is obvious that in certain instances it is advisable to attempt a cure without cutting the hair short in order to obtain the cooperation of the patient.

Case 3—L. S., a woman aged 19, was born in Italy. She contracted favus of the scalp nine years before, previous to coming to the United States. Examination disclosed only two small patches on the scalp in which there was marked atrophy and moderate inflammation with crusting. Positive results were obtained by the fluorescence test, by the direct mount, and by culture, confirming the diagnosis of favus of the scalp. Treatment by means of local applications and manual epilation of diseased hairs at intervals of three or four weeks resulted in the finding of only two infected hairs after four months and none thereafter. Four months later no evidence of activity was present, although there was marked atrophy of the scalp at the sites of the prior infection.

We have records of scalp infections due to *A. schoenleini* in 10 children during the past year, all of these patients showed localized patches of recent origin. Cure was obtained in every case by using various local applications combined with manual epilation at regular intervals. In each case the disease was eradicated within three months, and later observations revealed no recurrences.

The fact that cure may be obtained by means of epilation with forceps, combined with topical applications, should be kept in mind as a possible method of treatment in cases of recurrence following x-ray therapy. We advise the concomitant use of salves to prevent

FIG 1, CASE 1 Aspects of a case of favus under treatment (A) Thick crusts (scutula) covering almost the entire scalp are partially obscured by the vigorous growth of hair (B) Small follicular crusts on the right leg (C) Six weeks later the scalp is free of crusts Treatment consisted of the daily use of a sulfur ointment, frequent shampoos, and the removal of loose crusts by forceps on her infrequent visits to the clinic Many infected hairs still remain The scalp is now ready for x-ray therapy (D) Three months after the epulating dose of x-rays a few infected hairs are discovered when the scalp is examined in filtered ultraviolet rays These hairs are removed by forceps (E) Nine months after the x-rays were given no infection is present and there is marked regrowth of hair Small areas of atrophy scattered over the scalp are well concealed

fection involving almost the entire scalp but with less crust formation than in the case of her sister's scalp Fluorescent hairs were demonstrated on most parts of the scalp except over the occiput Microscopic and cultural studies verified the diagnosis of favus

(3) Two children in the family of her sister (M M), a girl of 6 and a boy of 4, had infections

of the scalp, in both instances limited to small areas In both cases cultures proved the diagnosis of favus The father of the children was uninfected

Had a definite effort not been made, it is unlikely that the disease as it affected these 5

PRACTICAL OPERATION OF PRESERVED BLOOD AND POOLED PLASMA PROGRAM IN THE SUBURBAN HOSPITAL*

J. W. EHRLICH, M.D., F.A.C.S., White Plains, New York

EACH issue of each medical journal presents us with certain new procedures. Many are desirable, some seem indispensable, and in their incipency are the function of our large teaching hospitals. The vast majority of patients, however, are cared for in the average 100- to 200-bed hospitals. Therefore, any advance to be enjoyed by the general public must be adapted to practical use in the suburban or smaller urban hospitals.

The advantages of a preserved blood program were obvious to us, and in February, 1939, at the request of the Surgery Director a trial bank program was started at the White Plains Hospital. This has progressed satisfactorily and today includes a preserved plasma program, which has been accepted as a legitimate and necessary department of our hospital and furnishes preserved blood and plasma for several nearby hospitals.

I review here the essential details of this program, the stumbling blocks encountered, and the methods of avoiding these, together with the evolution of this project into its present mature state, with the hope that it may stimulate the introduction of similar programs in hospitals of comparable size. The practical aspects of such a project are stressed.

Organization

The blood and plasma bank should be initiated and operated by a team consisting of a clinician, a pathologist, an experienced laboratory technician, and a competent graduate nurse experienced in operating room technique. The team should be headed by the clinician or the pathologist. Each member should understand every detail in the operation of the program.

Established blood banks in the vicinity should be visited by the entire group. If none is operating locally, a visit to the nearest large hospital bank should be arranged. An understanding of the work of Elliott,¹ DeGowin,^{2,3} and their contemporaries is invaluable. Scudder⁴ and Bull and Drew⁵ furnish analytic data which aid in a broader understanding of changes in stored blood and

plasma. Douglass⁶ thoroughly reviews the entire subject of blood transfusion.

Equipment

During the last year there has been made available commercially a system of prepared sterile vacuum bottles adaptable to each step in the program. These are relatively inexpensive and have simplified the entire procedure to such an extent that we now consider home-made systems and containers used in the beginning as impractical for the smaller hospital. The system can be operated entirely as a closed one, practically eliminating all possibility of contamination. Together with the technical accessories necessary for use, it has been found thoroughly efficient after months of operation and is described herewith.

The following containers are all hermetically sealed, sterile, and nonpyrogenic. They are capped with rubber stoppers that are covered with two rubber diaphragm seals. A metal cap covers these. Each container is used once only.

Fig 1(A) shows the vacuum transfusion bottle containing 70 cc. of 2½ per cent sodium citrate in physiologic saline solution, capacity over 500 cc., used to withdraw blood from the donor. Blood is stored in these bottles and transfused from them.

Fig 1(B) shows the vacuum centrifuge bottle, empty, capacity over 250 cc., used for centrifuging plasma aspirated from outdated blood in the transfusion bottle. This bottle may also be obtained with anticoagulant solution so that blood may be withdrawn directly and centrifuged for plasma immediately. (This avoids transfer from transfusion bottle.) This bottle is designed to fit into a trunnion cup for centrifuging, described below.

Fig 1(C) shows the vacuum pooling bottle, capacity 1,000 or 2,000 cc., into which is aspirated the plasma after centrifugation from the centrifuge bottles. Pools of plasma from four bloods or less are collected in the 1,000-cc. bottle, and pools from four to eight require the larger 2,000-cc. bottle.

Fig 1(D) shows the vacuum plasma bottle, containing 250 cc. of normal saline, capacity over 500 cc. Approximately 250 cc. of plasma from the pooling bottle is aspirated into the vacuum plasma bottle, which is then stored as dilute pooled plasma and from which plasma is transfused.

Fig 2(A) shows a micrometer valve and needle which may be completely disassembled for clean-

the spread of the infection and to bring about a mild inflammatory condition of the scalp as an aid to epilation. Medicinal topical treatment is not alone curative in this form of scalp infection

Aftercare When X-Rays Are Used—Following an epilating dose of x-rays, boric acid ointment (U S P) may be applied to the scalp morning and night. This prevents the development of crusts and limits the spread of infection from one follicle to another. The use of ointments or other preparations containing mercury, sulfur, and many other drugs should be avoided during the first three weeks following the exposure to roentgen rays. After three weeks when the hair begins to loosen it is permissible to prescribe an ointment containing 5 per cent ammoniated mercury. A more complete epilation may be assured by the application and immediate removal of strips of adhesive. We strongly advise against leaving adhesive applied to the scalp overnight or for any extended time, since this increases the likelihood of spread of the infection and often brings about pustulation and favors secondary infection. At this and subsequent visits the patient should be observed under the filtered ultraviolet rays. About two or three months after the epilating dose has been administered is a crucial time, since there are almost always infected hairs which then make their reappearance and, if left, will bring about a recurrence of the disease (Fig 1D). Manual epilation in filtered ultraviolet rays is sufficient to eradicate these limited numbers of diseased hairs. The patient should not be discharged until there

have been two examinations, one month apart, with negative results

Summary

Many cases of favus of the scalp show neglect due to ignorance of the patient or to partial relapse following inadequate or poorly controlled treatment. The slow onset and mild symptoms may mask the disease for months or years. Treatment requires special consideration of the nature of the infection but cure may be confidently expected.

Case-finding should be attempted by examination of the other members of the family and other close contacts or associates to trace the origin of the infection and to bring all cases of the disease under treatment. The patient with favus of the scalp should also be examined for lesions of the nails and of the glabrous skin.

Preliminary treatment by means of ointments is advisable to soften and remove the crusts on the scalp. Unless the crusts are all removed, further treatment may be ineffectual. If only localized patches of the scalp are involved, manual epilation may be sufficient to remove the infected hairs. X-rays may be used to produce a defluvium in cases of widespread involvement. The proper after-treatment following a depilating dose of x-rays is important to bring about cure and prevent relapse of the infection.

MEETING OF SCIENTIFIC PHOTOGRAPHERS

The Biological Photographic Association, an international group of photographers in the natural sciences, will hold its eleventh annual meeting in the Hotel Buffalo, Buffalo, September 11-13.

The program, in which a number of outstanding photographers and other technical experts will participate, emphasizes this year methods and processes which are likely to contribute to the national defense.

The annual salon, now well known to photographers through the pages of the photographic magazines, will again be a prominent feature of the meeting. Visitors are welcome.

For further information write the Secretary of the Biological Photographic Association, University Office, Magee Hospital, Pittsburgh.

DRESS REHEARSAL AT FIRST-AID POST

One of the first-aid posts in London which has not received a sufficient number of casualties to satisfy its large and zealous staff has, under the direction of its medical officer, instituted a system of faked casualties, which are attended with the same care and routine as if they were from an actual incident, says the *British Medical Journal* for February 1. An elaborate "make-up" has been introduced under the direction of a quartermaster who is skilled in this art, and the work is carried out as carefully as anything done behind the scenes at a theater and is as realistic in its results. Cellophane, vaseline, and various colored dyes are used to give a close resemblance to the appearance of a raw wound, and in the case of one of the frequent "victims"—an orderly with histrionic gifts—the resemblance is assisted by his disordered movements and mutterings.

found willing to pay their obligations in part by donating a pint of blood. Therapeutic bleeding of selected hypertensives at periodic intervals constitutes an additional source of supply.

Once in operation, blood for the bank is secured from relatives or friends of patients requiring transfusion. They should be contacted as soon as transfusion is decided upon or before that time in critical cases where blood or plasma transfusion is anticipated. Many operative cases are instructed to furnish donors on admission. Frequently, two or three will present themselves and we have had as high as a dozen volunteer blood for a critical patient who was employed by a company such as the American Legion, firemen, local police, and state troopers frequently will volunteer. Ideally, they should come in on a fasting stomach of at least four hours. Blood taken thus is less likely to exhibit food allergens, which may cause reaction, if such blood is used later for plasma conversion, such plasma will appear clearer because of reduced lipemia. This clarity is chiefly of aesthetic advantage and not practically significant in our experience. Donors who admit recent ingestion of garlic or gin, or whose breath suggests this, should be rejected, since both may cause

transfusion reactions. In the operation of a small bank it is recommended that donors be bled as soon as they present themselves, even though they may have ingested food a short time earlier. If this is not done, there will be a certain donor loss with ensuing difficulty in keeping a sufficient supply of blood on hand. Donors are questioned and checked over physically to conform with state regulations.¹⁴ Although it is doubtful whether active syphilis can be transmitted by transfusion of preserved blood, a donor is rejected where a history of syphilis is obtained or the scar of a healed chancre is found, even though he may have had adequate treatment and the Wassermann reaction is negative. Experiments in progress elsewhere⁷ suggest that blood inoculated with spirochetes and refrigerated loses its infectivity after ninety-six hours or less.

Collection of Blood

Blood may be withdrawn by any member of the house staff. We have delegated this procedure to a graduate nurse. At night or in odd hours a house staff member substitutes. The donor is bled in a special room delegated exclusively to this program, where no distractions, such as emergency cases coming in, can upset his equanimity. It is well to

Fig 1(A) Vacuum transfusion bottle, (B) vacuum centrifuge bottle, (C) vacuum pooling bottle, (D) vacuum plasma bottle

Fig 2(A) Micrometer valve and needle, (B) filter and drip unit

The needle may be plunged through the rubber diaphragms and thick rubber stopper of any of the vacuum bottles. The valve head is tightened or loosened to regulate exactly the desired vacuum pull during any transfer process.

Fig 2(B) shows a stainless steel mesh filter with drip unit, used in both blood and plasma transfusions.

Fig 3(A) shows a blood-taking set (donor set). This includes the following: micrometer valve,

rubber tubing, glass adapter, 16-gage needle, novocain, 2-cc syringe, clamp, tourniquet, and dressings, all contained in a tray.

Fig 3(B) shows a blood-giving (or plasma-giving) set (recipient or dispensing set). This includes the following: stainless steel filter and drip, Y tubing allowing for attachment of two bottles, tubing and needle set for vein, novocain, syringe, and accessories, all contained in a tray.

Fig 4 shows an aspiration set for plasma conversion, note the 6-inch, 12-gage aspirating needle. In addition, the set contains the following: micrometer valve and tubing, air-filter unit, clamp, glass graduate, and wrench for tightening needle on micrometer valve, all contained in a tray.

Details of preparation and assembly of these sets are given below under "Preparation of Equipment." Note that each system is sealed within itself, with ends rubber-capped until opened up to use. At least three taking sets and three giving sets should be kept ready for use at all times. Only one aspiration set for plasma conversion need be kept in readiness.

The vacuum centrifuge bottles fit into brass trunnion cups, which are suspended from a special centrifuge head (Fig 5(A)). These are available commercially and fit the standard No 1 International Centrifuge found in most laboratories.

An accurate trip balance for balancing centrifuge bottles in trunnion cups is also necessary (Fig 5(B)). These are part of the average hospital's laboratory equipment.

Requirements for the refrigeration necessary to this program are given under "Preservation."

The Donor Problem

In the beginning, blood for the bank is obtained from volunteer donors on the attending staff, the house staff, or the nursing staff. Charity patients who have recovered will be

that the blood is ready for use. If the Wassermann is reported positive, the blood is immediately withdrawn from the bank to be discarded or used for routine laboratory work, and this is noted on the record card. Occasionally, it is necessary to use blood before a Wassermann has been reported, and in this case the hypersensitive, quicker Laughlen test is done. Should this be reported positive the blood is not used until the Wassermann is reported. Our blood loss due to positive serology has been 3 per cent, and this is our chief reason for discarding blood. Other reasons are failure to secure sufficient blood for tests in the pilot tube and suspected contamination due to poor technique in taking blood.

When a transfusion is proposed, the laboratory types the patient and cross-matches his blood with that in the pilot tubes from a bottle of the same group or an acceptable group in the bank. Group O recipients may be given only group O blood, group B may be given group B or group O, group A may be given group A or group O, group AB may be given AB, A, B, or O. If type AB blood is to be used for transfusing, both the donor's and recipient's bloods are subgrouped and properly cross-matched as A_1B or A_2B if original cross-matching is not compatible. Subgrouping and proper matching of A_1 and A_2 should likewise be done when donor A and recipient A bloods do not cross-match. Absorbed B serum for this purpose is commercially available. Lundy⁶ reports the highest incidence of untoward reactions with those group AB recipients who are transfused with group AB blood and fewer untoward reactions when any of the other three groups are transfused to a group AB recipient. Despite this, most clinicians will still demand type AB blood for type AB recipients. Lundy also states that the cross-matching of blood has not been found necessary, and it is not done at the Mayo Clinic except where a history of untoward reaction to a previous transfusion is obtained. The work of Levinson and Cronheim⁷ on absorption of isoagglutinins is interesting in this connection. We still insist on cross-matching as a check against our original typing. Diagnostic typing serums of known high titer (at least 1 to 40) are used. This is prepared from pooled donors' serums and in our experience gives quicker agglutination than most commercially available serums for typing (with the exception of one, now available, which we have titrated as giving agglutination at a dilution of 1 to 320 within five minutes).

When the compatibility of the blood has

FIG 8 Giving blood

been determined, the bottle, with one record card attached, is sent to the patient's bedside. The duplicate record card is retained for the blood bank file, and data identifying the recipient is annotated thereon. Pilot tubes are held for twenty-four hours for any additional check should the patient experience a reaction.

Transfusion of Preserved Blood

Actual transfusion is routinely done at the patient's bedside, unless the need for dissection and exposure of a vein seems necessary or in the case of an infant when the procedure may be done in the operating room.

The blood-giving (recipient) set (Fig 3(B)) is opened and assembled by the transfusing physician, usually a member of the house staff. The blood bottle is inverted, assuring a mixture of cells with plasma, and connected to the set as in Fig 8. Sets are so arranged that either physiologic saline or blood can be infused interchangeably. The tubing is cleared of air with saline, thus avoiding blood waste. As soon as the saline is dripping and the needle is fixed in the vein, the blood is cut in and the saline clamped off. Should the red cells pack in the lower part of the bottle or the filter, thus slowing the drip, saline is again cut in, flushing the tubing and,

FIG 6 Taking blood from donor, bottle should be gently agitated

have the table tilted slightly with the head low. The arm is prepared with iodine and alcohol, and a tourniquet or blood pressure cuff is applied. The nurse dons sterile gloves, a taking set (Fig 3(A)) is opened and assembled, and the needle is inserted into an ante-cubital vein. The micrometer valve is opened, allowing just sufficient vacuum action to pull over a steady jet of blood, which drops into the citrate solution in the vacuum transfusion bottle (Fig 6) during collection. When the required amount has been withdrawn the tourniquet is released, and the micrometer valve is screwed down tight shutting off the vacuum. The needle is withdrawn from the blood bottle stopper which seals itself. The needle is withdrawn from the donor's vein and then held over a pilot tube (test tube) containing 1 cc of a 2½ per cent sodium citrate solution, and a few drops of blood are allowed to drop in for cell suspension for typing. Two cc of blood is allowed to drop into a second pilot tube to clot for cross-matching, and the balance (at least 5 cc) is drained into the third tube for the serologic test. These tubes are placed in a rubber collar rack attached to the blood bottle (Fig 7(A)). The name of the donor is written on adhesive strips, one is attached to each pilot tube and one to the bottle of blood. Duplicate record cards are filled out and attached to the bottle, which is immediately placed in the refrigerator. The donor is given an ounce of whiskey or a pint of milk, as elected, and is kept at rest or in a sitting position until we are certain

FIG 7(A) Pilot tubes in rubber collar rack, (B) "fibrin foam" topping blood

that his cerebrum has become adjusted to a reduced blood volume. A fainting donor is a poor advertisement for the project. The time required for collection of blood is usually five to 10 minutes.

Preservation

Any type of automatic refrigerator may be used, whether powered by electricity or gas. There must be no oscillation from vibration of the refrigerating mechanism, for agitation of the cells is undesirable. A temperature setting of 2 C is satisfactory. An inexpensive maximum and minimum recording thermometer is hung inside, and each day the technician notes the range during the previous twenty-four-hour period and sets the markers back with a magnet. Current shutoff or inefficient operation of the refrigerator is thus detected. When defrosting becomes necessary the blood should be transferred temporarily to another refrigerator, avoiding agitation. A most satisfactory unit that keeps the temperature variation to within 1 C of the desired setting is now available. This refrigerator is made especially for blood banking and is conditioned for humidity so that defrosting is never necessary.

Laboratory

Each morning the technician types all bloods received during the previous twenty-four hours, noting the type on the two record cards. One card is replaced on the blood bottle in the refrigerator, the other card is placed under the appropriate type number in the "incomplete" section of the blood bank file. A Wassermann is run and, if reported negative, the record card is so marked and transferred to the "complete" section of the file under the appropriate blood type, indicating

trate saline solution blood may be infused effectively at twenty days. If the plasma program is adopted and used, it is possible for even the smaller hospital bank to have fresh blood on hand without the costly procedure of throwing away outdated blood and paying professional donors for replacement.

Plasma Conversion

The blood bank file is checked once weekly for outdated blood, and the bottles themselves are checked for specimens showing advanced hemolysis even though not outdated. These are removed for conversion to plasma. Conversion is done in the special blood-plasma room, and sterile precautions are observed by the workers.

Whether pooling of plasma is a valuable precaution against serious reaction in the occasional plasma of high agglutinin titer is a moot issue at this time. Using a closed system where an additional process does not increase the possibility of contamination, we have elected to do pooling, with plasma from 4 to 8 pints or more of blood making up one pool. Where pooling is not done, a single aspiration step replaces steps two and three to be described below.

Where blood is taken primarily for the purpose of turning out plasma, it should be withdrawn from the donor into the vacuum centrifuge bottles containing citrate solution, and a single aspiration step then replaces the three described below. If in this situation pooling is done, two aspiration steps will be necessary.

It is noteworthy that the Baxter vacuum system for pooling and transferring plasma, which is described here, was considered safest in connection with the Blood-Plasma-for-Great-Britain Project, sponsored by the Blood Transfusion Betterment Association.¹¹ It is also significant that no contaminations are recorded with a uniform system completely closed from donor's vein to final plasma bottle.

Aspiration—Step One

The plasma aspiration set (Fig 4) is opened, and the bottles of blood selected are transferred from the refrigerator to the plasma conversion room, avoiding agitation.

The remaining vacuum in the blood bottles is exhausted with the ingress of filtered air. The unit for this purpose consists of an 18-gage needle attached to the barrel of a 10-cc syringe packed nearly full with absorbent cotton (Fig 9(A)). The entire unit has been autoclaved previously as a part of the plasma

FIG 10 Transfer of plasma from blood to centrifuge bottle

aspiration set. The needle is passed through the rubber stopper, with the thumb held over the open end of the barrel to control the sudden inrush of air. The thumb is gradually released, completely neutralizing the negative pressure within the bottle.

A vacuum centrifuge bottle (Fig 1(B)) is required for the plasma from each 500-cc bottle of blood. The metal cap is removed from the former, and with the micrometer valve cap closed down tightly its needle end is plunged well through the rubber stopper. The aspirating needle, connected with the other end of the rubber tubing, is plunged through the blood bottle stopper, with the tip just below the plasma surface, and the micrometer valve is opened, withdrawing the plasma (Fig 10). It is permissible to draw over some cells during this step (this being of no consequence since these will be thrown down later with centrifugation after which a second aspiration is done).

This first aspiration step is done successively with each bottle of blood to be converted to plasma.

Centrifuging

The centrifuge bottles containing plasma are next placed in the special trunnion cups (Fig 5(A)), which have been chilled previously in the refrigerator. These must be in absolute balance on opposite sides of the centrifuge head. The importance of this cannot be overemphasized. To accomplish this, a trip balance (Fig 5(B)) is used, and any inequality in weight is eliminated by the ad-

FIG 9(A) Air-filter unit (for releasing vacuum),
(B) detail of transfer assembly

if necessary, diluting the blood in the bottle just sufficiently to break up the packing. It is advisable to agitate the blood bottle a few times during the transfusion, thus preventing cell packing. Rarely when blood has been improperly taken, "grape jelly" consistence of the blood clogs the filter. Cutting in saline will usually clear the system again but, if more blood of jelly consistence is noted in the bottle, this should be discarded and another bottle should be cross-matched, the vein meanwhile being kept open with saline. "Fibrin foam" (Fig 7(B)) may also bog the filter. This comes from excessive agitation of the bottle during the operation of taking blood, from taking blood too rapidly, from an air leak in the taking system, or from other improper taking technic.

Blood is never warmed, since hypercritical temperature may effect irreversible reaction of its protein constituents. The bottle may be allowed to stand at room temperature for one to two hours before giving, if desired. We have not observed ill effects from giving cold blood at average speeds. At least thirty minutes is consumed in infusing 500 cc of blood unless the patient is in *extremis*. The rate of administration can be varied with the drip tube clamp and by the size of the needle. Blood (or plasma) is always filtered, although plasma may be given subcutaneously or intramuscularly without filtering. When infusing more than one bottle of blood to a patient at one time, we take the precaution of cross-matching each blood with each other one, as well as with the patient, although this is not universally considered necessary. After transfusion the record card is completed by

the transfusing physician, identifying the recipient and noting any reaction, and turned in to the record room. Any reaction is also noted on the laboratory record card. A transfusion sheet is filled out and attached to the recipient's hospital chart.

Outdated Blood

The most frequent question arising in connection with the preserved blood program is "how long should the blood be kept?" In our experience the period of sufficient viability for effective use in transfusion is not constant. Earlier reports by the Russian workers cite transfusion of blood three to four months old. Originally, we used blood six to eight weeks old without ill effects. An important criterion is the presence of excessive hemolysis, which can be gaged macroscopically by the degree of "pinkness" in the plasma just above the interface between the cells and plasma line. Some bloods will show minimal hemolysis at four weeks, other bottles will show "pinkness" within forty-eight hours. We attribute the marked discrepancies to a variation in the technic of withdrawal and to variations in the physiologic chemistry of the donor. Excessive or insufficient agitation, improper sealing in the taking system, allowing air to bubble through the tubing with the blood, the need for stopping during withdrawal to change needles or veins, while partial clotting takes place in the tubing, and complete exhaustion of the vacuum before finishing withdrawal—all may contribute to increased red cell fragility. Perusal of the literature shows general agreement that relatively few significant changes occur before five to seven days. In discussing the age limit, it should be understood that fresh blood is still used for certain morbid conditions where the tissue in its unchanged state is desired. But in shock and acute hemorrhage—operative, postpartum, or spontaneous in origin, so frequently the indication for transfusions in the suburban hospital—it seems ridiculous to quibble about the value of blood that is immediately available, whether a few days or even a few weeks older than it ideally should be. The number of white cells, prothrombin value, potassium content, and electrophoretic pattern of proteins in a pint of blood being transfused under such circumstances are obviously of little importance when the alternative is delay that may be fatal.

The average age of preserved blood infused here is under seven days. Alsever¹⁰ states that with the use of his special dextrose ci-

late solution into the pooling bottle by vacuum to cover the entire batch.

We have been furnishing plasma to other institutions where it is held for emergency use, and we cannot predetermine the period of storage and, therefore, observe our control cultures for three weeks before releasing any plasma from the pool. To date we have not observed any positive cultures, and we have had no reason to discard any plasma. Seventy-two-hour negative cultures are satisfactory if the plasma is to be used within a reasonable time. Plasma is stored under refrigeration.

Dilute plasma, after standing for a period, may show fibrin veils or shreds. These are dissipated by shaking but may reform with standing. They are removed in filtration, and all plasma should be filtered with the same technic as described for blood transfusion. A turbid appearance of the plasma from certain pools may be ascribed to lipemia existing at the time the blood was originally withdrawn. Thus and the pinking due to hemoglobin in solution are of no concern in administration in our experience. Refrigerated plasma will appear turbid. This is greatly reduced after standing at room temperature for a short time.

Like others, we have had absolutely no reactions of any type from the use of plasma.

Reactions

By far the largest number of reactions from blood transfusion and nearly all reactions from uncontaminated plasma transfusion and intravenous infusion of solutions result from the presence of pyrogenic substances in the infused mediums or in the equipment used therefor. Their prevention is so predominantly important that certain principles set forth by Walter¹² are summarized below. The preparation of our equipment is based on these principles.

Since standardizing our present system, blood transfusion reactions have been reduced to less than 8 per cent and none could be construed as pyrogenic. They were classified as allergenic or hemolytic. We have had no fatal or permanently untoward reactions to date. The majority of our reactions occurred where fresh blood was used. Approximately 10 per cent of our transfusions are still done with fresh blood, the chief indications being puerpera and other dyscrasias, as well as infectious and leukopenic states.

Untoward reactions to transfusion have been noted more frequently in febrile cases, in infected pelvic cases, preoperatively and

postoperatively, and in postoperative hysterectomized patients. It is believed that garlic or gin ingested by donors prior to bleeding is a source of transfusion reactions.

Pyrogenic Reactions and Their Avoidance

Walter¹² explains in detail the principles for prevention of reactions due to impurities in solutions and the apparatus used for intravenous therapy with particular reference to pyrogens. Strangely enough, an accurate concept of the nature of pyrogens is of no interest to many physicians and is ignored by many in responsible positions on nursing staffs. Walter emphasizes that the safety of intravenous fluid administration depends upon a clear understanding of the meaning of the term "chemically pure" and its differentiation from the word "sterile."

Our experience here, with a limited staff for investigative purposes, has led us to the conclusion that the commercially available parenteral fluids, while slightly higher in cost, infinitely simplify our problems, reduce the number of technical assistants required, and obviate the transient flurry of reactions so common in many hospitals when one or more of the trained technical assistants are absent or on vacation, with a subsequent break in the meticulous technic which is essential. Regardless of whether solutions for intravenous therapy are prepared by the hospital or are obtained commercially, the accessory apparatus for administration (needle, tubing sets, filter, etc.) must be prepared so as to be "pyrogen-free" as well as sterile. Centralized responsibility for cleanliness and preparation is indispensable. The pertinent principles underlying elimination of pyrogens and their reactions are herewith restated.

1. Chemically pure distilled water will not cause reactions when injected intravenously.

2. Such water is readily contaminated and rendered pyrogenic by air-borne bacteria.

3. Berkefeld filtration does not remove the offending substance.

4. Pyrogens are filterable, thermostable exotoxins, removable by proper distillation.

5. To remain pyrogen-free, water must be hermetically sealed in sterile containers.

6. Purity of distilled water at the source must be checked frequently.

The common decolorization test with sulfuric acid and KMnO_4 is of little value in detecting amounts of pyrogen in water which may be responsible for intravenous reactions. The following tests are of significance.^{12,13}

1. Biologic: the distilled water in question is made to approximate physiologic concentration of sodium chloride and injected into the marginal ear vein of carefully controlled rabbits. Variations in rectal temperature should not exceed $1/2$ degree (F), which is considered physiologic.

2. pH: this may vary between 5.5 and 7.0.

Fig 11 Transfer from pool to final plasma bottle

dution of water to the cup until the indicator remains absolutely stationary at exactly zero

Centrifuge for one hour at 2,000 revolutions per minute, tachometer reading. With this weight the rheostat reading is not reliable. Five to ten minutes are required to get up speed and again to decelerate. The brake on the centrifuge must not be used in decelerating. Because of the terrific throw and the serious consequences of anything "letting go" during centrifuging, it should be an inflexible rule that this cannot be done except under supervision of a laboratory technician familiar with the procedure. After centrifuging, the bottles containing plasma are removed without agitation to the refrigerator, where they are held for not less than twelve hours, insuring settling of cells from any swirl induced while the centrifuge decelerated. A thin, solidly packed line of cells will be visible at the bottom of each bottle. Pink color in the supernatant fluid represents hemoglobin in solution in the plasma and is not objectionable.

Aspiration—Step Two—Pooling

After standing for twelve hours (usually overnight) in the refrigerator, the bottles are taken out without agitation. A plasma aspiration set (Fig 4) is opened and the proper size vacuum pooling bottle (Fig 1(C)) selected, depending on the number of centrifuge bottles of plasma to be run through as one pool. For a pool of four or fewer, a 1,000-cc pooling bottle is used, for from four to eight, a 2,000-cc bottle is used. The outer rubber diaphragms are removed from the centrifuge bottles containing the plasma, and the remaining vacuum in these is released with the air-filter unit described under "Aspiration—

Step One" (Fig 9(A)). The aspirating needle, rubber tubing, and micrometer valve assembly is again used, this time for transferring the plasma from the centrifuge bottles to the single large pooling bottle. Care must be exercised to avoid drawing over any of the packed red cells at the bottom of each centrifuge bottle. We waste only a few cubic centimeters of plasma from each centrifuge bottle (about 1 per cent) by careful teamwork during this aspiration. The tip of the aspirating needle in the centrifuge bottle must be advanced slowly as the plasma is pulled over, and the aspiration must be done extremely slowly as the red cell line is approached. If the tip of the aspirating needle is kept in contact with the side of the centrifuge bottle, less agitation of cells is likely during the aspiration and a better yield is obtained. As the cell line is reached the bottle may be tipped gently to advantage. Until the technic is perfected it is safer to waste even 10 to 15 cc of plasma rather than risk pulling over any cells in this step. This is important, because typing is not done before plasma transfusion and incompatible red cells can cause reactions.

When all the plasma has been transferred to the pooling bottle, this is inverted, mixing the plasma.

Aspiration—Step Three

Vacuum plasma bottles (Fig 1(D)) each containing 250 cc physiologic saline are used for the final aspiration, 250 cc of plasma from the pooling bottle is aspirated into each plasma bottle with the same type assembly as was used for the previous aspiration (Figs 9(B) and 11). During this final step it is necessary to release the mounting vacuum in the pooling bottle once or twice, using the air-filter unit described above. Each bottle now contains 500 cc of dilute plasma under partial vacuum. A few cubic centimeters are always left in the pooling bottle for a pool culture. If the finished dilute plasma is not to be used promptly, 5 cc of 1 per cent aqueous merthiolate solution is added to each bottle of 500 cc, giving a concentration of 1 to 10,000. This is accomplished immediately after the plasma has been pulled over from the pooling bottle by closing the valve, removing the aspirating needle, and inserting it into a graduated closed container of merthiolate. The valve is then opened, drawing over the merthiolate by vacuum. The valve is then closed and withdrawn with its attached needle. The rubber stopper seals itself. An alternate method is to draw a sufficient quantity of 1 per cent merthio-

late solution into the pooling bottle by vacuum to cover the entire batch.

We have been furnishing plasma to other institutions where it is held for emergency use, and we cannot predetermine the period of storage and, therefore, observe our control cultures for three weeks before releasing any plasma from the pool. To date we have not observed any positive cultures, and we have had no reason to discard any plasma. Seventy-two-hour negative cultures are satisfactory if the plasma is to be used within a reasonable time. Plasma is stored under refrigeration.

Dilute plasma, after standing for a period, may show fibrin veils or shreds. These are dissipated by shaking but may reform with standing. Centralized responsibility for cleanliness and preparation is indispensable. The pertinent principles underlying elimination of pyrogens and their reactions are herewith restated.

1. Chemically pure distilled water will not cause reactions when injected intravenously.

2. Such water is readily contaminated and rendered pyrogenic by air-borne bacteria.

3. Berkefeld filtration does not remove the offending substance.

4. Pyrogens are filterable, thermostable exotoxins, removable by proper distillation.

5. To remain pyrogen-free, water must be hermetically sealed in sterile containers.

6. Purity of distilled water at the source must be checked frequently.

The common decolorization test with sulfuric acid and KMnO_4 is of little value in detecting amounts of pyrogen in water which may be responsible for intravenous reactions. The following tests are of significance.^{12,13}

1. Biologic the distilled water in question is made to approximate physiologic concentration of sodium chloride and injected into the marginal ear vein of carefully controlled rabbits. Variations in rectal temperature should not exceed $1/2$ degree (F), which is considered physiologic.

2. pH this may vary between 5.5 and 7.0

Fig 12 Capped system, completely closed for autoclaving

If these values are exceeded at either end, a carry-over of foreign substances in the still, such as ammonia, creosote, etc, is to be suspected

3 Electrical resistance of the water or its reciprocal, the conductance the values here may vary from 0.8 to 1.2×10^{-6} reciprocal ohms. This test also serves chiefly as an indication of an ineffective or improperly operated still.

Of the above, the first test is by far the most important. However, all should be repeated periodically on all solutions used for intravenous therapy and on water or solutions used for cleansing and preparation of apparatus used in connection with intravenous therapy. Their importance in the blood plasma program cannot be overstated. Many smaller hospital laboratories are not equipped or not disposed to perform these tests and, where this is true, recourse must be had to commercial laboratories.

Preparation of Equipment

Pyrex glassware or its equivalent should be used throughout because its stable annealed surface resists hydrolysis. Glassware must be free of original soil as well as of cleansing agents and alkalies, dried blood, bacterial growths, or dried fungi. After cleaning and final rinsing in preparation, the apparatus must be autoclaved at once or the entire preparation repeated. A responsible nurse who will faithfully carry out in meticulous detail the following routine is a "must" in this program.

After transfusion of blood or plasma (or infusion of intravenous solution) the entire set is immediately disconnected and immersed in a large basin of cold tap water for at least ten

minutes to loosen up blood and detritus in the system. Each piece is then individually washed by holding it under running water until it is grossly clean. Tubing is held up to the light and flushed until no dark areas are visible. If rubber tubing is soft it is discarded and a new length substituted. The micrometer valve is disassembled and thoroughly cleansed with freshly distilled water. The screw threads of the micrometer valve are anointed with two drops of glycerin and the head is screwed back half way. Stainless steel mesh filter is placed in fuming nitric acid for a period of one-half to twelve hours, varying with the amount of dried blood present on the mesh. Then it is removed with forceps and rinsed for at least fifteen minutes under tap water by placing the open end over the spigot. It is then allowed to stand in a cup of freshly distilled water for not less than fifteen minutes and placed on a towel to dry. Following this, it is flushed through with freshly distilled water and incorporated in the giving set with continuation of the technic as described. Needles occasionally become clogged and are cleared by flushing through with 12 per cent ammonia solution by means of a syringe. Each piece of the entire system is laid in a basin of freshly distilled water for not less than five minutes, and the system is then assembled and flushed through with freshly distilled water by gravity. Following this, it is flushed through with commercially obtained normal saline, also by gravity. The needle end of the micrometer valve is plunged through a rubber stopper into a glass vial, and the tip of the Luerglass adapter at the other end of the system is covered with a rubber cap (Fig 12). This keeps the system closed, in that steam for sterilization is generated from water in the residual saline of the flushing and no steam from the autoclave itself enters the system, thus avoiding another source of potential entrance of pyrogens. Each system is placed in a tray, wrapped in a double sheet, and immediately autoclaved at 20 pounds pressure for twenty minutes. If autoclaving cannot be done immediately, the entire routine must be repeated. Taking sets, giving sets, and plasma conversion sets are handled in this manner. A vacuum transfusion bottle or vacuum plasma bottles are also placed in the appropriate set for autoclaving so that the outside is sterile and better technic can be maintained during the operations of taking blood or converting to plasma. New glassware, needles, filters, and micrometer valves do not require special treatment other than the preparation listed above. Rubber tubing specially prepared at the source is obtainable commercially. All foreign material within the lumen has been removed previously and, when new prepared tubing is substituted, no treatment other than the above described is required.

We have found it impractical to autoclave rubber tubing more than six times. It softens up so that the pull of the vacuum is likely to cause

collapse, slowing up the operation of taking blood or interfering with steps in plasma conversion. In addition, the rubber in the lumen tends to stick and is difficult and time-consuming to free when cleaning. We discard it before this stage is reached.

Intravenous accessory equipment and needles are prepared with the same technic and, since its inauguration, no intravenous reactions have been reported.

Records

Before submitting to blood withdrawal, each donor is requested to sign a permit.

New York State requires the hospital to keep detailed and accurate records of all blood transfusions.¹⁴ This is extended by interpretation of our local board of health to apply to plasma transfusions as well. The state likewise requires that a physical and serologic examination of the donor be made. Records for this purpose are filled out in duplicate by the taking physician and accompany the blood to the refrigerator. After the blood is typed, one card is placed in the open file under the proper type denoting availability. When blood is used this card is retained by the laboratory for its permanent files, and the other card is sent to the record room where its data are posted in detail in a large permanent record book, details on both the donor and recipient being entered. In addition, a transfusion sheet giving the pertinent data is filled out and attached to the recipient's hospital chart.

A perpetual inventory sheet is attached to the refrigerator, and available blood and blood awaiting serologic report are listed under headings "complete" or "incomplete." When blood is issued or received, an entry is made in the appropriate column under the actual date of the transaction, so that at any time the "assets" of the bank may be determined at a glance.

Economics

This program entails a minimum investment in permanent, nonexpendable equipment of about \$100 for such items as valves, filters, special centrifuge head, and trunnion cups. Other equipment is expendable and purchased as needed.

Our cost of expendable (consumable) equipment is approximately \$1.50 per transfusion of whole blood. This includes the vacuum bottle containing citrate solution, a complete set for taking and giving blood, including a vacuum bottle containing 500 cc of physiologic saline, whiskey or milk when elected by the donor, and a 10 per cent break-

age allowance. This figure does not include laboratory costs, hospital overhead, or the time of the operating room nurse in preparing equipment. On a similar basis, the cost of expendables is approximately \$2.75 per transfusion of 500 cc of dilute plasma including the cost of taking blood originally, conversion to plasma, and administration. Where blood is taken directly for plasma conversion, one step is eliminated, and the cost of expendables drops to approximately \$2.25. If pooling is omitted, this figure approximates \$2.00.

Hospital Charges

Patients' accounts are charged at professional donor rates for whole blood for each transfusion of blood or plasma given. They are credited in kind when friends or relatives replace the blood or plasma. Patients are also charged for the laboratory work of typing, cross-matching, and serology, this figure varying with their status in the hospital. In addition, they pay a service charge covering the costs of the sets used in taking and giving blood and plasma. This service charge replaces the larger charge formerly made when blood was taken and given in the operating room and, likewise, varies with the patient's accommodations in the hospital.

Value of Program

Since blood and plasma have been made readily available their use has increased rapidly. Not only has the number of patients receiving transfusion increased but the number of transfusions given to the individual patient and, frequently, the amount of blood per transfusion have increased. Thus, the bleeding but resectable intestinal carcinoma patient may receive not the usual 500 cc but twice, thrice, or many times that amount if clinically desirable.

During the year preceding the institution of our bank program, fewer than seventy-five transfusions were given. In 1939 the figure rose to 161, 1940, to 306, and a monthly increment continues. In this connection it should be noted, however, that in December, 1939, the Hospital moved into new quarters and the average daily census increased from ninety-six in 1939 to 150 in 1940.

Several neighboring hospitals now use blood and plasma from our bank, thus increasing the turnover and assuring fresher blood for all.

Conclusions

1 The advantages of a preserved blood

and plasma program in an average suburban hospital have been brought out

2 The practical aspects of inauguration, operation, and management of such a program have been described

3 The simplicity and facility of the closed vacuum system have been emphasized The use of such a system has been shown to be foolproof in our hands and, by inference, in any small hospital No contamination, no untoward reactions with permanent sequelae, and no fatal outcome has been encountered

4 The adaptability of such a system for blood preservation with plasma conversion or for direct plasma production has been stressed and is independent of quantitative turnover

5 The achievement of such a program is dependent upon meticulous detail in preparation of accessory equipment used with the vacuum bottles, in centralization of control of the entire program, and in fullest departmental cooperation within the hospital

6 After the initial equipment has been obtained, the program is entirely self-sustaining,

and sufficient additional income can be provided from its operation to justify constant improvement in technical equipment and the addition of newer "wrinkles" as these are introduced

AMERICAN COLLEGE OF SURGEONS TO HOLD CLINICAL CONGRESS IN BOSTON

The thirty-first annual Clinical Congress of the American College of Surgeons will be held in Boston from November 3 to 7, with headquarters at the Statler and Copley-Plaza hotels. The twenty-fourth annual Hospital Standardization Conference sponsored by the College will be held concurrently. About five thousand surgeons and hospital executives from all parts of the western hemisphere are expected to gather in Boston for these meetings, the program for which will include clinics and demonstrations in local hospitals and medical schools, as well as scientific sessions, conferences, medical motion picture showings, and exhibits in the headquarters hotels.

The chairman of the Board of Regents of the American College of Surgeons is Dr. Irvin Abell, of Louisville, and the president is Dr. Evarts A.

Graham, of St. Louis. The president-elect is Dr. W. Edward Gallie, of Toronto, who will be inaugurated at the presidential meeting and convocation to be held the evening of November 3 in Symphony Hall, when several hundred initiates will be received into the fellowship of the College. In charge of local arrangements for the Clinical Congress is a committee of Boston surgeons headed by Dr. Leland S. McKittrick, chairman, and Dr. Richard H. Sweet, secretary.

Headquarters of the American College of Surgeons, which has a fellowship of more than 13,000 surgeons, are at 40 East Erie Street in Chicago. The associate directors are Dr. Bowman C. Crowell, who heads the Department of Clinical Research, and Dr. Malcolm T. MacEachern, chairman of the Administrative Board and in charge of hospital activities.

PRIZE OFFERED

The American Neisserian Medical Society announces an annual prize of one hundred dollars, to be known as the P. S. Pelouze Award, to be presented to the person under thirty-five years of age who, in the opinion of the Committee of Awards, has made the outstanding contribution to the control of the gonococcal infections during the preceding year.

Nominations for the award should be sent to the Secretary, 475 Commonwealth Avenue, Boston, not later than March 31 of each year. The winner will be announced at the subsequent annual meeting of the Society.

WOMAN'S AUXILIARY—ONONDAGA CO

The Onondaga County Medical Society and its Woman's Auxiliary are planning a luncheon on Tuesday, September 23, 1941, at the Hotel Syracuse, Syracuse, New York, as part of the program of the regular Fifth District Meeting of the Medical Society of the State of New York. An entertainment is being planned to follow the luncheon, and the doctors' wives as well as the doctors are cordially invited to attend this function.

Reservations Dr. Sabine, Little Falls, or Virginia B. Marty, 301 Summit Avenue, Syracuse, New York.

PHYSICAL DEFECTS IN THE GENESIS OF JUVENILE DELINQUENCY

FRITZ BLUMENTHAL, M D, Warwick, New York

PHYSICIANS are sometimes concerned with the physical aspect of disease and defect to the exclusion of adequate consideration of the influence that disease or physical defect may have on the personality and behavior of the patient. Medical work in a school for delinquents offers a challenging opportunity to investigate the correlation of physical abnormalities and behavior problems.

This paper is based upon studies of adolescent, delinquent boys who present, besides the problem of delinquency, a physical abnormality that appears to be related to the delinquency. The question is whether there is a mere coincidence of physical defect and social maladjustment or whether there is a causal relationship between the two.

The fact that one boy at State School whose hip ailment allowed him bicycle riding as his only sport activity repeatedly stole bicycles certainly points to obvious motivation. It still remains to be learned why this boy became delinquent, since it cannot be assumed that every individual suffering from such a disease presents inevitably the same behavior problem, nor can it be said that every boy who acutely desires a bicycle steals one. However, the mere statement of the above sequence gives us some understanding of the behavior of a boy deprived in his play life and seeking, a little desperately perhaps, to retain a grip on the only form of active play remaining for him.

When we consider physical defects in their effect upon adjustment and character, we must consider them as they appear to the patient. The deformity of a broken nose may mean little to a pugilist but may spell tragedy to a debutante. It seems to be appropriate to differentiate between those defects that are conspicuous and deforming and those that are easily concealed. However, it is psychology rather than visual conspicuousness which is important, and the two are not always parallel. For instance, deformity of the genitalia is easily concealed but is usually conspicuous in the mind of the patient.

There are physical conditions that are linked to the personality in ways much more

direct than the defects discussed here. Among the most important of this group are certain organic diseases of the nervous system and imbalance of the endocrine glands. These conditions may cause changes in personality and may influence behavior through nervous or hormonal effect rather than merely through the personality reaction to the defect.

Adenoidal condition in school children has been ascribed to be the cause for behavior problems. Whether there is a direct causal correlation or whether both the inattentiveness or instability of those children and the adenoidal condition are due to constitutional factors is still an open question.

Among the sensory organs, the eye is of outstanding significance. As far as psychic reactions are concerned, diseases of the eye are in many cases more obvious and visible than those of the ear. Diseases afflicting the auditory apparatus frequently cause gradual deterioration to which the patient becomes more easily adjusted than to the shock of an accident with sudden alterations. People with impaired hearing may show traits of mistrust, seclusion, and paranoid tendency, being asocial and withdrawn, but such changes come on in middle age and delinquencies rarely result. The reverse is frequently true in the eye cases. The following is an illustration.

Case Report

Case 1 — James, a Negro boy aged 16, was admitted to State School after his second court appearance on the petition of his mother, who complained that he was ungovernable and beyond her control. The history of birth and early development was normal. He was reported by his mother to have been no problem in his earlier years. His conduct and work at school were considered good. His mother is separated from her husband, who is suffering from alcoholism. James was brought up by his mother since his ninth year. About that time the family moved from the South to New York.

At the age of 13 James fell on a piece of iron on the street and sustained an injury to his right eye and a deep laceration over the bridge of his nose. A year later, while boxing with a friend, he suffered an additional injury to the same eye. It was necessary for the eye to be enucleated. A prosthesis was substituted. James became extremely sensitive about the glass eye, feeling it

From the Neurological Institute, New York City and the New York State Training School for Boys, Warwick, New York.

was noticed and ridiculed by everyone. He resented being called names like "one-eye" or "half a face" by the children. His behavior was more babyish than before the accident. James became increasingly unmanageable in the home and school. He was disobedient and quarrelsome and had temper tantrums. On one occasion he struck his sister with a stick of wood. He frequently stayed out late at night. The school reports that he was a habitual truant and was considered a menace to the safety of the other children.

On admission to State School, James was found to be a tall, well-muscled boy of normal intelligence. In addition to the prosthesis in the right eye socket, he had a scar extending from the bridge of the nose to the lateral third of the right eyebrow, disfiguring his face. He complained of frequent pain in his testicles, a condition that he claimed to be a contributory cause for his outbursts. Physical examination of his genitalia revealed a tight foreskin with partial phimosis.

James was found to be a bright boy with some insight and mature manners, who discussed his difficulties freely. He was interested in music, dancing, dramatics, and sports.

At State School he readjusted himself progressively and with excellent results. The phimosis was treated by surgery, and he made no more complaints relative to his genitalia. In regard to his eye condition, he was given individual treatment by the clinic worker. The result is shown in the following statements of the boy given in an interview. He said that he had gotten used to the idea of having the other boys refer to him as "one-eye" or "half a face." He stated that he had come to the conclusion that the boys meant no harm, and he answered as if he were being called by his own name. He saw other boys with infirmities who accepted them as such, and he knew that nothing personal was meant. James said that he could see that his major difficulty in facing the boys at school was caused by his accident and, if he had felt then as he did now, he would have had no difficulty. His truancy he laid directly to the fact that he did not want to face the taunts of his classmates.

James was paroled after a six months' stay at the institution.

Chronologically speaking, there appears to be a relationship of physical defect and delinquency. The changes in the boy's behavior closely followed the accident and its physical manifestations, and the relation between his improved behavior and his adjustment to his handicap made it unlikely that this could be by mere coincidence.

However, the problem is not so simple as this might imply. James was brought up under unfavorable conditions by a mother who is very much concerned about her own

problems. She considers her marriage a mistake and hates her husband whom she seems to have presented as a bad example to James. Furthermore, James feels that his mother prefers his sister to him and that both sides together against him. Then, there is the move from the South to the North with a complete change of environment. Consequently, it could be assumed that this boy would have become delinquent even without a physical handicap, particularly at the age of puberty when marked changes in behavior occur even under normal conditions. One may come to the conclusion that James tried to put the blame for his delinquent behavior on a physical defect which only precipitated the boy's development toward delinquency. To some extent such a psychologic reaction can be traced in every case of physical defect and delinquency. It is not an uncommon experience that individuals try to excuse their failure in facing and handling difficult situations in life by their physical ailments or defects. Careful study in each case is required to evaluate the importance of the physical defect in comparison with other factors involved. The elimination of a physical handicap does not benefit some patients who only too soon find something else to explain or excuse their failures. This group of individuals resembles the patient who travels from hospital to hospital and "enjoys" dozens of operations on his "adhesions." However, where the physical handicap is remediable the attempt should be made to correct, eliminate, or control the condition if it is amenable to treatment.

Two aspects of this case deserve further mention. The loss of his eye occurred at the age of 13, at a time when the boy had a rather fixed conception of his own physical personality. Suddenly he became different not only to others but also to himself. This meant readjustment, even of his conception of himself. In the words of Lauretta Bender¹ "The pathologic process results in a discrepancy between the body structure and the body image constitutionally and socially acceptable to the patients."

Another important aspect of this problem has been elaborated by Alfred Adler,² who has stressed the feeling or complex of organ inferiority. An individual suffering from a physical defect and striving to hold his ground in environment with his will to power overcompensates his imperfections in his feelings and actions toward others.

Insecure and ridiculed by his mates, James

tried to protect himself, tried to gain status, by being tough and disobedient. On the other side, he liked to be babied but exploited the attention of others in order to tyrannize over them. It was thus the way of least resistance for James because of the rejection by his mother and her apparent identification with her husband, with whom she had been so unhappy.

The influence of the attitude of the parents can be decisive upon the child's response to his handicap. Parenthood throws a strain on human wisdom and adaptability under any circumstances. In the case of a handicapped child, any emotional imbalance in the attitude of the parents may cause reactions that are stronger and more vehement than in normal children. The child's helplessness may stimulate excessive care and protection. This in turn is an excessive burden on parents. Furthermore, overprotection can become the expression of feelings other than love. Parents may feel ashamed of their handicapped child. Such bitterness will be readily followed by feelings of guilt because they should not be ashamed. Consequently, the parents overdo in their care for the child, they become overprotective. This overprotection then may be called a "reverted rejection." And a child, rejected by the family, may easily react by seeking to obtain status outside his narrow environment—his home. Where the neighborhood shows a large population of delinquents, delinquency may become the channel for the child's satisfaction. A child thus rejected by the family may become delinquent when accepted by a group of lower standards. However, a child who is rejected by the wider circle of the outside world but well accepted by the family has a greater chance of escaping delinquency. Such a child, loved and understood by his parents, may develop to "the problem child" in a different way and often with a better prognosis.

The last outstanding important link in the chain of causes and sequences—the anticipated improvement of the boy's conduct and behavior immediately following the elimination of the physical handicap by medical procedure—is illustrated in the following case.

Case Report

Case 2—William was admitted to the institution at the age of 16 with a record of seven court appearances, including six for burglary and one for truancy.

The boy is reported to have been cross-eyed since childhood. The father had deserted the

home recently, and the mother is a religious fanatic who was married twice. The father used to punish William by putting him in a dark cellar. It is perhaps significant that the mother believes that the boy's eye trouble originated in this practice. William was operated on for strabismus twice at the age of 13, but without success. In connection with the eye operations, William tells of his father visiting him every night in the hospital. His mother did not come because she could not bear seeing him with his eyes bandaged, whereas William refers to the treatment by the nurses as being "babied," which he nevertheless found pleasant.

William is reported to have been poor in his school work in which he showed little interest. However, he had lost considerable time in his school program because of his long stays at the hospital. William did not participate in sports, because he "could not see well," but he sought his satisfaction in other fields—for instance, in drawing. The boy did not try to compete with the group of his own age but was inclined to associate with older boys. He used to walk out of school, but in summertime he had done hard work, such as cutting down trees and sawing wood. He said of himself "I worked more than I stole."

William is a rather tall, well-built boy, alert, but of limited intelligence. He had a marked strabismus, and the lid of the left eye blinked constantly. In interviews he appeared to be uninterested and cringy, was shy, and showed embarrassment about his condition of which he was self-conscious. He would look at the floor when speaking and try to draw away. He admitted his delinquencies without hesitation but was inclined to regard them lightly. While he accepted constructive criticism with an outward display of appreciation, he failed to profit by it in work. He liked to volunteer, but his good intentions, it was felt, were promoted by a selfish motive.

The boy's behavior changed grossly following a correctional operation for strabismus, which was successfully performed at State School. The correction of the physical handicap enabled the boy not only to overcome his shyness and embarrassment but also was followed by his feeling genuinely sorry over his past offenses and repeating frequently that one would never find him in any other institution. William was now able to meet people, he had become an excellent sport and was anxious to make a good impression in his assignment.

After his discharge from State School he made an excellent social adjustment, holding a position with a telegraph company in which he is doing exceedingly well. He has maintained this good adjustment for two years on parole.

In contrast to the first case, this second case deals with a correction of a defect that had existed throughout the early years of the

boy's development Physical imperfections may be congenital or may be acquired Their influence on personality can be of a wide range, depending greatly on the moment in which they appear and on the time the physical alteration takes to become evident to the patient and others Physical imperfections may prove to be the determining factor in a child's psychologic maldevelopment, or they may stimulate his reactions toward life as a precipitating, contributory factor In consequence, it cannot be expected in every case that with the elimination of a physical handicap that has existed for a number of years deviations in behavior will vanish and that the experiences of early childhood, which are important for the development of personality and character, can be completely wiped out Concerning the reactions of older age groups to physical defects, the sad experience of a war is doubtless providing too many examples of the problems of personality, as well as of economic adjustment, of persons suddenly crippled

Rejection is one of the possible reactions of the important people of the environment to a handicapped child Pity is another response, also dangerous to the child's development

Case Report

Case 3—Frank, a boy aged 14, of Italian descent, was admitted to State School after a number of court appearances, violation of probation, and commitment to another institution. He was presented to court first at the age of 11 for stealing a ride on a trolley car and then twice within a short period on petition of his father for running away from home, incorrigibility, and remaining out late at night His latest offense was stealing

The boy's behavior and conduct were considered satisfactory until the age of 8 The difficulties began following an accident Frank fell from a five-story building and sustained fractures of his legs and a fracture of the right side of his jaw Despite an operation at that time the jaw deformity remained, with a severe limitation of function as a consequence Frank became sensitive toward this malformation. He felt rejected by his father who held before him the older brother as a model child, even in respect to his appearance The mother seemed to have had a good deal of affection for Frank. She talked of his good looks as a child, contrasting it with his present undersized, puny appearance and malformation. Undoubtedly, she protected the boy from the father She expressed a great pity for her unfortunate child.

Frank was a small boy of borderline intelli-

gence There was an excess callus formation along the right ramus of the mandible which created a pronounced asymmetry of his face Ankylosis of the temporomandibular joint allowed only a limited forward-backward movement of the jaw This condition forced the boy to shovel food into his mouth with his fingers. The hearing of the right ear was impaired.

In an interview at State School Frank made the remark "I did not like the way I was and no one was helping me, so I decided to be bad" He had resented strongly that an agency that had him in its care before his commitment to State School had failed to keep what he considered its promise to fix his jaw The boy became cheerful when he was assured of another operation. In general, however, Frank showed a good deal of resentment against the world. He stated that he had never belonged to a club and had never joined a group of delinquents. He claimed that he had never stolen anything new or valuable He felt that the accident had impaired his mind somehow, and he attributed many of his difficulties to it Examination, however, failed to reveal evidence of organic damage to the central nervous system.

A second and third operation brought about an improvement in the boy's physical appearance and function of the jaw and was also followed by a change in the boy's attitude He began to show considerably more security In contrast to his forward and aggressive manners and lack of respect, he was polite and showed greater social interests

On parole Frank was apparently well adjusted for two years. At home he did not revert to the frequent running away that made him a problem before The absence of his older brother, who had married, and of his father, who was seriously ill in a hospital, probably contributed a good deal to the boy's adjustment in the home Their roles previously had been that of stern disciplinarians

However, Frank did not go to full-time school after his release He spent his time shining shoes in the neighborhood of his home and running errands on occasions Here he got under the influence of a group of delinquent boys whom he joined for "junking," a behavior that too frequently leads to forcible entry of buildings In view of the inadequate education this mentally retarded boy received after his release, it is not surprising to hear that Frank was finally involved in a case of burglary He was then committed to an institution for mentally defective delinquents

Being illustrative of the diverse factors contributing to a behavior problem, this case introduces borderline mental deficiency as a new constituent

The conflict with the father and older brother, as well as the high rate of delinquency in the neighborhood, may be noted

as aggravating factors, which have also been met in other cases

There is, however, one element worthy of mention in this case history, which, in a form both hidden and open, has exerted its influence. Pity was shown by the mother and, later, after his first unsuccessful operation, by his teachers. When Frank began to have some difficulties in school he acted up. One of the problems of the physician is that an illness or handicap that merits pity and, therefore, provokes it is likely to have as one of its results the development of the spoiled child, unable to stand on his own feet, resentful of authority, and almost doomed to frustration.

An appropriate answer to the question regarding the healthful attitude toward physical defect is given by Richard L. Jenkins: "I should say it contains, first, a recognition and acceptance of the fact of the defect and the degree of handicap it constitutes. I should say that the second element is a recognition of what is possible in spite of the defect, and here I mean what is possible without too extreme sacrifices or efforts. I should say that the third element is that the handicapped individual should shape his ambitions, should 'build his castle in Spain,' should lay his plans within the limits of what is possible with that handicap. Surprisingly enough, many individuals with extremely severe handicaps do succeed in preserving excellent mental health and apparently in finding a great deal of enjoyment of life despite many serious restrictions of their activities. A factor frequently of determining importance is whether the handicapped individual achieves social contacts which give him some sense of acceptance and social outlet."

In addition to this, a case quoted in the literature indicates how much depends on the attitude not only of the handicapped child but also upon training and education. Strict observance of a few simple pedagogic rules made it possible for a boy, born without arms, to train his feet to perform the work of hands. His father sought to require that the boy be given no pity and no unnecessary help.

In the time that has passed since this spectacular case, the problem of the handicapped child has become the subject of intensive investigation and of what is the imperative consequence of observation, help, treatment, and stimulation. Satisfactory results can be achieved if mental hygiene, psychology, and medicine, as well as social welfare, further develop their cooperation and undertake

more definitive integration in helping children with organic inferiorities in whatever way is indicated.

Summary

1 Physicians are sometimes concerned with the physical aspects of disease and defect to the exclusion of adequate consideration of the influence that disease or physical defect may have on the personality and behavior of the patient.

2 There are physical conditions that are linked to the personality in direct ways. Among the most important are certain organic diseases of the nervous system and imbalance of the endocrine glands.

3 There are physical conditions that have effects on personality and behavior through psychologic reactions to the defect.

4. It seems to be appropriate to differentiate between those defects that are conspicuous and deforming and those that are easily concealed. However, it is psychologic rather than visual consciousness which is important, and the two are not always parallel.

5 The adlerian theory of the inferiority complex and the theory of the discrepancy between physical structure and body image are believed to explain many problems of behavior in handicapped children.

6 A study of cases of delinquent boys with physical handicaps seems to indicate that delinquencies frequently have a close chronologic correlation both in origin and response to treatment. However, it cannot be expected in all cases that the psychologic features that have become established through a number of years vanish after corrective operations.

7 The influence of physical defect on personality depends greatly on the time in which it becomes evident to the patient and others. Physical imperfections may be congenital or may be acquired. They may prove to be the determining factor in a child's psychologic maldevelopment, or they may stimulate his reactions toward life as a precipitating factor.

8 Where the physical handicap is remediable the attempt should be made to correct, eliminate, or control the condition. This objective should not be followed with such blind enthusiasm as to result in the use of inappropriate treatment—for instance, surgical treatment for a condition of neurotic origin.

9 Environmental factors and their influence upon the behavior of the physically handicapped child must be understood and, where possible, controlled

WESTCHESTER'S SIXTEEN POINTS ON NEONATAL MORTALITY

For many years medical authorities in the United States have been working energetically to reduce infant mortality. In the last 15 years infant mortality in this state has fallen 50 per cent

The major causes of death among the babies who live less than thirty days are being born prematurely, being injured at birth, and congenital malformation.

Approximately 5 per cent of all babies born are premature. In 1939 Westchester had 330 premature babies born out of a total of 7,295 births, 88 of the 330 were stillborn.

How do Westchester's sixteen hospitals take care of premature babies? A survey, made by the public health committee of the Medical Society of Westchester County and summarized in the county newspapers, reports the following

In the New Rochelle and White Plains hospitals and in the Yonkers Professional Hospital there are separate nurseries for premature babies. In eleven hospitals there are incubators, in five there are none. Eight of the hospitals reported a total of fifteen nurses with special training in the care of prematures. Five hospitals, the United in Port Chester, St Agnes in White Plains, the Peekskill, Mount Vernon, and Dobbs Ferry hospitals have an obstetrician in charge of the newborn, in the other eleven hospitals there is a pediatrician in charge.

Of Westchester's 1939 premature babies, 219 were born in hospitals and 23 were born at home. Ten of these later were taken to hospitals. Sixty-one of the prematures died in hospitals.

Of the hospitals, in 1939 Mount Vernon, with 842 births, rendered the largest maternity service, Dobbs Ferry, with 93, the smallest.

The United Hospital, Port Chester, rendered the second largest service with 731 births, St Agnes, White Plains, third, with 625, and the New Rochelle Hospital, fourth, with 616.

Following this survey and its other work over a period of years, the Public Health Committee of the Medical Society of Westchester, made, as of April 1, 1941, the following recommendations for reducing neonatal mortality in this county

1 Prevention of premature birth. (a) Improve prenatal care of all prospective mothers (b) Avoidance of physical and emotional strain in pregnancy (c) Postpone induction of premature labor as long as possible

2 Vitamin administration to prospective mothers Vitamin D or multiple vitamins and calcium throughout pregnancy Vitamin K before delivery

3 Prenatal care of the breasts to provide for breast feeding

4 Exercise care in obstetric analgesia to avoid asphyxia neonatorum, especially use of morphine in second stage of labor

5 Avoid long second-stage labor in premature

deliveries Episiotomy and low forceps for delay on perineum

6 Care in handling newborn premature infants Special attendant to receive and care for prematures at birth Avoid chilling Use heated bassinette Oxygen and mechanical resuscitator when needed for asphyxia and transfer to incubator as soon as possible

7 Newborn infants and nursery in charge of pediatrician in cooperation with obstetrician.

8 Obtain more autopsies on neonatal deaths especially of premature infants Advise hospitals on suggested methods of approach to obtain permission for necropsies

9 Special study by hospital staffs of cause of neonatal deaths and improve care for newborn and premature Discussions by pediatricians, obstetricians, and pathologists

10 Vitamin administration to all newborn infants, especially to the premature Vitamin K on day of birth to all whose mothers have not had it Vitamin D (not in oil) within two weeks of age, also vitamins C and B

11 Establish a fund in each hospital to provide free breast milk for premature infants of needy families Breast milk may be purchased from Mothers' Milk Bureau of the Children's Welfare Federation, 435 Ninth Avenue, New York City, telephone ME4dillon 3-3105

12 Special training for nurses in care of premature infants (a) Arrange for courses at obstetric hospital teaching centers (b) One or more nurses with such special training in every newborn nursery in Westchester County (c) All nurses trained in care of premature, so listed for private duty at nurses' registries

13 Improved equipment for care of newborn and premature infants in all hospitals of Westchester County (a) More modern type incubators (b) Special nurseries for isolation of contagion. (c) Special nurseries for care of premature infants (d) Provide at least one ideal unit for care of premature infants in the county

14 Transport to hospital all premature infants under 4½ pounds born at home. (a) Provide portable ambulance incubators for transfer to hospital. (b) Provide hospital incubator care of such infants (c) Require, by sanitary code, immediate report to health authorities of premature infants born at home

15 Send copy of this report and summary of replies to questionnaires on care of newborn to each hospital superintendent and medical board of sixteen Westchester County hospitals Hold a meeting for discussion with hospital superintendents

16 Acquaint the public with the special needs for each hospital as determined from hospital superintendents, board of governors, and medical staffs

THE TREATMENT OF REGIONAL ILEITIS

HYMAN SNEIERSON, M D , F A C S , Binghamton, New York

SINCE the differentiation of regional ileitis from nonspecific granulomas of the intestine by Crohn and his associates in 1932,¹ a voluminous literature has been published. This has, in the main, corroborated the statements of these investigators while expanding some of their original concepts. The condition has been found in nearly all countries and types of peoples, and a review of case reports of previous years shows records of typical cases as early as 1806.¹ The original concept of a lesion limited to the terminal ileum has been expanded to include any part of the intestinal tract. Lesions limited to the right side of the colon are considered by some to be separate entities but this classification is not accepted by all.^{2,12}

Despite the general agreement on the clinicopathologic aspects, the treatment is still controversial. Up to the classic paper of Cutler¹³ radical surgery was considered to be the only treatment. The time and method were the only points about which opinions differed. Since Cutler's article, there has been a swing toward the palliative type of surgery. The subject, however, is far from settled, and this paper was undertaken with the idea of crystallizing the opinions of the medical profession in general and comparing them with the procedures used in 23 proved cases in Broome County, New York (Table 1).

An abstract of the subject of regional ileitis is also being presented prior to a discussion of the treatment of this condition so that the basis for the conclusions drawn will be clear.

Regional ileitis is a nonspecific, granulomatous condition of localized segments of the bowel, usually involving the terminal ileum. It is characterized by lymphostasis or blocking due to an unknown factor, possibly a virus. Attempts have been made to link this with tuberculosis, bacillary dysentery, a filtrable virus, and to various forms of streptococci without success.^{2,5,8,10,11}

The condition usually involves one segment. More than one portion may be affected, with normal intestine known as a "skip" area between. The areas involved may be in different parts of the ileum, in the ileum and jejunum, or in the ileum and colon. The skip areas may vary from a few inches to several feet.

Microscopically, the "pathological picture consists of a generalized inflammatory reaction with increased vascularity and swelling of the involved tissue with edema and cellular infiltration. The cellular infiltration is largely lymphocytic with plasma cells and eosinophils in moderate numbers. Eventually, the acute reaction is followed by fibrosis and invasion by giant cells, and a chronic process occurs as a part of the attempted healing process. The reactive areas now appear as small tubercles, similar, histologically, to those present in tuberculosis. No caseation occurs and no tubercle bacilli are found. As fibrosis increases, constriction of the bowel results and the wall of the intestine becomes a stiff tube with variable areas of great constriction which may almost totally obstruct the bowel."¹⁴ In the small bowel, as constriction progresses and as the blood supply and lymphatic drainage are interfered with, ulceration of the mucosa results. This ulceration occurs in the mesenteric side of the gut.

The gross appearance of the lesion is characteristic. The involved area is thickened and shows signs of a low-grade inflammatory process. The serosa is red and roughened with a markedly thickened mesentery containing enlarged but discrete lymph nodes. The demarcation between the normal and involved areas is abrupt. When the condition has progressed sufficiently there is ulceration of the mucosa on the mesenteric side of the gut. The marked fibrous reaction results in a thickened "hose-like" bowel, which may become almost completely obstructed in the late stages. The ulcerative process is usually slow, causing the formation of abscesses that are walled off by the surrounding bowel. Perforations into surrounding bowel causing enteric fistulas are frequent. Abscesses also may drain externally, forming abdominal, inguinal, lumbar, perianal and rectal, or rectovaginal fistulas. Occasionally, ulcers perforate directly into the peritoneal cavity, causing peritonitis. Because of the inflammatory reaction or abscess formation, a mass may be felt, usually in the right lower part of the abdomen. The condition is characterized clinically by remissions and exacerbations. When first noted, the affected segment may vary from a slight thickening to a condition impossible to differentiate from carcinoma.

TABLE 1—REGIONAL ILEITIS BROOME COUNTY, NEW YORK

Case	Age	Sex	Year	Acute or Chronic	Prior Appendectomy	Procedure	Abdominal Fistula	Recurrence	Clinical Result
1	49	M	37	Chronic	No	Primary resection	No	No	Cured
2	44	F	36	Chronic	Yes	Stage resection	No	No	Cured
3	19	F	36	Chronic	No	Primary resection	No	No	Died
4	22	M	37	Chronic	Yes	Stage resection, multiple operation	No	Yes	Surgical failure
5	17	M	36	Acute	No	Primary resection	No	No	Died
6	33	M	36	Acute	No	Ileostomy and drainage, 2-stage resection	No	No	Cured
7	26	M	33	Chronic	Yes	Primary resection	Yes	Yes	Improved
8	47	F	36	Chronic	Yes	Mikulic's procedure	No	No	Cured
9	34	M	35	Chronic	Yes	Primary resection	Yes	Yes	Cured
10	22	M	30	Chronic with acute obstruction	Yes	Primary resection	No	Yes	Improved
11	57	M	39	Chronic	No	Primary resection	No	No	Died
12	21	F	39	Acute	No	Primary resection	No	No	Cured
13	27	F	38	Acute	No	Primary resection	No	No	Cured
14	12	M	39	Acute	No	Primary resection	No	No	Cured
15	38	F	37	Acute	No	Drainage	No	No	Cured
16	14	F	36	Acute	No	Appendectomy	No	No	Cured
17	17	M	35	Acute	No	Appendectomy	No	No	Cured
18	4	M	38	Acute	No	Appendectomy	No	No	Cured
19	55	F	37	Acute	No	Appendectomy	No	No	Cured
20	19	F	39	Acute	No	Appendectomy	No	No	Cured
21	60	M	39	Acute	No	Appendectomy	No	No	Cured
22	15	M	40	Acute	Yes	Freeing adhesions bleeding ulcer	No	No	Cured
23	48	M	40	Chronic	No	Appendectomy	No	No	Cured
					No	Medical treatment	No	No	Improved

Clinically, the condition has been divided into four stages.² For practical purposes it is sufficient to know that the condition first causes signs of inflammation and irritation of the bowel. This is the stage at which acute appendicitis is diagnosed and the appendix removed. Diarrhea, if present, should suggest the possibility of ileitis prior to operation. Later, the condition of obstruction and abscess formation with the appearance of fistulas occurs. Any one or all of these signs may be present. The early stages are considered to show low-grade obstruction, whereas the late stages show the more complete obstruction and the presence of fistulas or abscess formation.

Treatment

The treatment of regional ileitis is controversial because the etiology is obscure. Because of this unsettled condition, the aim of treatment must necessarily be empirical. There are two schools of thought based upon differing opinions as to the ultimate results.

The advocates of medical treatment are led by Dr Elliott Cutler, professor of surgery at Harvard University. Dr Cutler bases his opinion on a survey of the literature and analysis of 11 operative cases.¹⁸ Nine of these showed active recurrence. The complete cures reported by those using radical surgery are questioned by him. In the hands of his colleagues and himself, recurrence is a frequent happening. He feels that spontaneous recovery may occur apparently at any time and that surgery will change the outcome very little. He quotes 2 patients, with appendectomies

only and proved ileitis, who are active and in good condition, one after twenty-seven years. He advises against surgery unless such action is forced by obstruction or perforation. When necessary, surgery should be directed to the correction of the acute condition only. Resections are not indicated in his opinion. He suggests that permanent ileostomy may be the procedure of choice.

Crohn, who originally described ileitis, feels that medical treatment is dangerous. He states that ileitis is a cicatrizing disease that, by its very nature, results in distortion of the intestine. While patients with acute ileitis may recover completely, there is no way of knowing whether this will occur or whether it will progress to the chronic type necessitating radical surgery. He states that in proved cases seen at autopsy there has never been a complete cure pathologically. When the disease is diagnosable by x-ray, he believes that the defect will always need surgical resection. He quotes a case that was treated medically despite definite signs of ileitis and that subsequently had to have a radical resection.¹²

Before going into details as to treatment, it is necessary to emphasize that nearly all acute cases and a great many of the chronic ones are not diagnosed prior to laparotomy. In our series, only 2 of the 22 surgical cases were correctly diagnosed preoperatively. In some others, fistula formation pointed to the correct diagnosis but only after appendectomy had been done. It is useless to discuss treatment unless the diagnosis is sure. This is emphasized by the fact that 2 additional cases,

clinically and roentgenologically definite (having the "string" sign), were found to be due to appendiceal pathology and not ileitis. Cutler mentions a case that was treated for two years as ileitis and was then found to be due to malignancy.¹⁶ Therefore, we must divide cases into those diagnosed before operation and those only determined after laparotomy. This of itself determines that the bulk of the cases will be first seen by the surgeon, and the type of treatment followed will be his responsibility. In the larger clinics the correct diagnosis will be more often correctly made but, as stated above, these will be the advanced types showing definite deformity of the bowel by x-ray.

Medical treatment consists of general supportive measures to build up the patient and the use of a simple, bland diet, exactly like that used in tuberculosis of the intestine. Cutler suggests liquid petrolatum when signs of low-grade obstruction are present. A high-protein, high-vitamin, low-residue diet is indicated. Blood transfusions, sunlight, bed rest, and symptomatic medications are to be used. The use of nonspecific therapy has not been of much value. X-ray therapy is suggested by Cutler in cases that are resistant to other types of treatment.

Surgical treatment may be divided into treatment of the various stages of the disease. The acute ileitis, showing signs suggestive of an acute abdomen without obstruction, perforation, or abscess formation, is best left alone according to all writers. These are inadvertently found at operation for some abdominal condition, usually an acute appendix. There is free fluid in the abdomen and signs of an active lesion. The terminal ileum is thickened, the serosa may be covered with tubercle-like formations, and there may be enlarged discrete lymph glands. The appendix may or may not show signs of an inflammatory process. The removal of the appendix is a debated point. Crohn,⁷ Crile,²³ and others feel that the appendix should be left because of the danger of fistula formation. It is a common occurrence and many cases are cited in nearly all series. Woolsey²⁴ and others feel that routine appendectomy is indicated.

The use of radical resection has been advocated since regional ileitis has been known. This has been used for cases that are diagnosed prior to operation or cases in which the lesion and condition of the patient suggested the procedure. Radical surgery may be performed in one or more stages. Colp and Ginzburg recently reported 22 cases in which ileotrans-

versecolostomy, with exclusion only, was done with no mortality. They believe that removal of the diseased segment is not necessary except in cases with abdominal fistulas. Fistulas between segments of bowel have healed spontaneously after this procedure. Other writers are not so optimistic. Marshall¹³ and Crile²⁶ feel that resection of the affected segment is necessary. They believe that this should include a good margin of normal bowel above and below, including the lymphatic supply. Crohn suggests that the adjacent cecum and, possibly, ascending colon be removed when the terminal ileum is involved. Most of the writers use the side-to-side anastomosis with ileotransversecolostomy following the resection. All advise resection of the ileum with exclusion when short-circuiting procedures are used.

Cases having abscess formation should be treated conservatively. Marshall reports 1 patient who died following drainage. Usually the condition will subside after drainage, however, and radical surgery may be performed at a later date if desired. The treatment of patients showing signs of acute peritonitis carries a high mortality. Querna¹⁴ and Marshall¹³ each report a case in which ileocolostomy was performed with a fatal outcome. The general opinion is that the patient should be treated for the peritonitis primarily and that the ileitis should be left for a later date. Kross¹⁷ reports a case in which ileostomy only was performed with apparent cure.

The mortality in radical surgery is quite high, 15 per cent according to Crohn. He stresses that when palliative procedures with a lower mortality are used only 50 per cent are successful. The rest require further surgery with a correspondingly increased death rate. The high mortality in resections is attributed by him to the fact that cases are seen after extensive involvement has occurred due either to medical treatment or to failure to diagnose the condition. Clark and Dixon⁹ report 44 cases of which 14 had ileocolostomy only, with 4 deaths, 14 had a one-stage resection, with 1 death, 15 had a two-stage resection, with 2 deaths, and 1 had a simple exploration with recovery. Blackburn and his associates²⁰ report 16 primary resections and 4 two-stage resections without mortality. Two other cases with ileocolostomy only had equally good results. Russell²⁵ reports 27 cases of which 13 had resection with ileotransversecolostomy, 3 had a Mikulicz procedure, and 11 had appendectomy only, with 3 deaths. These varying reports are paralleled by other large series in the literature.

Crohn states that there is a 90 per cent return to health when radical resection is done. This is a positive statement corroborated by the writers quoted above. The discrepancy between this and Cutler's statement of no cure lies in the method of interpreting the patient's clinical status. Crohn relies on the fact that the patient is clinically well and is able to carry on his occupation. Cutler makes use of the x-ray interpretation by the "motility" series and classifies as cured only the case that has absolutely no intestinal symptoms and a normal gastrointestinal tract as evidenced by careful examination.

Crohn¹² states that the recurrence rate in his series was 7.7 per cent. This is attributed to too conservative resections. Marshall, Blackburn, and many others feel the same way. They state that many cases classified as recurrences are really progressions of the disease in a segment that has been left. In cases with skip areas, the diseased proximal segment may be missed at the first operation. Blackburn reports no recurrence in 22 cases. Marshall¹³ reports 2 recurrences in 29 cases.

In the treatment of regional ileitis the consensus is that, except in acute conditions, surgery is indicated. The type of surgery to be used will depend upon the pathology found at operation. Fistula formation always requires radical resection before cure is to be expected. Ileocolostomy with exclusion carries a lower mortality and apparently carries as good chance for complete recovery. Primary radical resection has given better clinical results than two-stage procedures reported in the literature. The type of procedure, however, will vary with the dexterity of the surgeon, and the results quoted above closely resemble each other no matter what type of surgery is used.

Analysis of the 23 cases in Table 1 shows that 22 had surgical treatment.

There were 13 acute cases. None of these were diagnosed preoperatively. One case (21) had had a previous appendectomy. He showed signs of acute obstruction and was operated on with this diagnosis. At operation, the terminal 2 feet of the ileum showed acute inflammatory changes. Treatment was restricted to exploration. Another case (15) showed signs of peritonitis but without any definite focus. Treatment was restricted to drainage. Six cases were operated on with a diagnosis of acute appendicitis and, although the appendix showed no signs of serious pathology grossly and microscopically, it was removed. None of these have developed a fecal fistula to date. Case 18, which showed ex-

treme thickening of the terminal 18 inches of the ileum in a 4-year-old child, has a good possibility of further trouble since only two years have elapsed. One case (6) had abscess formation. This was drained and an ileostomy performed. Later, he had a radical resection. The 4 remaining acute cases had primary resections with 1 death. This occurred in the operating room in a case with acute peritonitis complicating the ileitis. This was the only fatality in the whole acute group (7.7 per cent). The surviving cases are clinically cured.

Analysis of the treatment of the acute cases indicates that results in this type will be superior to that in the chronic case because the pathology is less advanced. Simple appendectomy, drainage, or exploration resulted in cure in 9 cases without a death. Primary resection in the remaining 4 cases resulted in cure in the surviving 3, but 1 died, giving a mortality of 25 per cent. This suggests that primary short-circuiting would be preferable.

Nine cases (1, 2, 3, 4, 7, 8, 9, 10, and 11) had had symptoms for some time and are classified as chronic. Only 2 cases were diagnosed before the first exploratory. One of these cases (1) was admitted with signs of acute obstruction, which subsided by use of Wangenstein drainage. At operation, despite negative x-ray findings, a small area of thickened bowel, which almost completely obstructed the ileum about 2 feet above the ileocecal valve, was found.

Six of the 9 cases had had previous appendectomies (66 per cent). Of these, 2 had fistula formation beginning two months after apparent normal healing (33 1/3 per cent). The record of 1 case (7) was not available, having been operated on elsewhere. The other case (9) was operated on for gangrenous appendicitis, but the microscopic report shows perianal appendicitis only. Another case (2) had drainage of an appendiceal abscess and an appendectomy which, on microscopic examination, showed a chronic inflammatory process only. Of the remaining 3 cases, 8 and 10 showed a mild catarrhal appendicitis at operation grossly. The last case (4) showed a definite involvement of the terminal ileum, which was considered to be tuberculous. Appendectomy was done as a routine procedure. Analysis of the 6 cases is enlightening in that not one of these, despite the operative diagnoses, showed signs of acute appendicitis microscopically. While there is no reason to doubt the possibility of a coincident appendicitis and ileitis, its frequency seems question-

able In the case with abscess formation it seems clear that the abscess was not of appendiceal origin

A comparison of these 6 with the 6 acute cases with appendectomy only reveals a great similarity as to the microscopic findings The greater severity of the gross findings in those requiring further surgery is important in that it suggests the key to treatment Had the terminal ileum been examined, it is possible that an advanced pathologic process might have been found unlike that in the acute cases The 2 cases that showed fistulas on admission (Cases 7 and 9) had had a postoperative diagnosis of gangrenous appendicitis In both, healing was normal and fistula formation did not occur until two months later The appearance of fistula formation after appendicitis as a sign of regional ileitis has been emphasized in the literature I feel that the appearance of fistulas in cases presenting evident gross and severe pathology in the appendiceal region is significant It suggests, as borne out by Table 1 and literature, that appendectomy in early mild cases is safe and that cure is to be expected

Analysis of these 6 cases from the point of view of treatment at the time of the appendectomy is of no value in 5 cases, since the condition was unrecognized However, it emphasizes the necessity for examination of the terminal ileum whenever possible

Case 4 is extremely valuable as it embraces the very points about which there is controversy In part, it supports both sides We have here a definite pathologic condition of the terminal ileum which was recognized at the time of operation Being considered of tuberculous origin, the patient, even though the diagnosis was incorrect, was treated according to the accepted ileitis regimen, with sunlight, fresh air, vitamins, etc The question over removal of the appendix was unimportant, since no fistula or difficulty followed which could be attributed to this Despite this treatment that follows Cutler's ideas, the patient developed extensive involvement of the small bowel and most of the large bowel over a period of three years It is paralleled by the case reported by Crohn¹² On second admission, he showed signs of acute obstruction plus extreme debilitation The condition was recognized prior to operation but the process was so extensive that an ileosigmoidostomy was the only procedure feasible The patient improved somewhat but still had complaints and was physically unable to work Resection of the affected bowel was then performed

His condition remained about the same, but gradually over a period of a year he became much worse He was seen by Crohn who felt that he would improve and advised against further surgery He could find no signs of active ileitis at the time Despite this optimistic report, the patient became much worse and was bedridden for a great deal of the time Mentally, he was difficult to handle Following Cutler's suggestion¹⁴ a permanent ileostomy was done He became marasmic because of the loss of intestinal contents and was completely bedridden An ileocolostomy was done with some improvement The patient was discharged from the hospital in as bad, if not worse, condition than when he entered Removal of a lymph gland from the mesentery of the ileum at the time of the last operation showed signs of active ileitis A month later, the patient returned, having been suffering from pains in the operative area He was definitely worse and showed a marked elevation of temperature The wound broke open forming a fecal fistula He improved for a few days, and then over a two months' period he failed and died This fatality is not included in the surgical deaths Analysis of this case strongly urges that surgical intervention be made when the condition is of a chronic nature—that is, grossly demonstrable In this the statements of Crohn,¹² Marshall,¹³ and others are corroborated On the other hand, the statement of Cutler that ileitis cannot be eradicated by radical surgery is suggested by the finding of acute ileitis two years after a radical operation and after the patient had been declared clinically cured A valid criticism is that he had too much surgery In our opinion, however, it would be true to say that he had surgery too late

Case 1 has been mentioned previously Primary resection of the ileum with side-to-side anastomosis resulted in a clinical cure This is contrary to what Dr Crohn prophesied when the case report was submitted to him He felt that the terminal ileum and cecum should also have been removed Mixer,¹¹ however, feels that it is not necessary to resect the terminal ileum and cecum at the same time unless there is actual involvement Case 14 was similarly treated with clinical cure

Case 3 gave a definite history suggesting regional ileitis Following primary resection with side-to-side anastomosis, impairment of circulation of the bowel in the area of the anastomosis occurred A second operation for obstruction and further resection resulted fatally This is a technical outcome that may

occur in any intestinal procedure and is one of the reasons for a preliminary short-circuiting as suggested by Colp and Ginzburg.¹²

Case 11 was operated on with a diagnosis of malignancy, and primary resection with side-to-side anastomosis was performed. Death occurred during convalescence from embolism. Embolism is a too common occurrence in bowel resections to warrant comment. Again preliminary short-circuiting is suggested as safer.

A résumé of the 22 surgical cases reveals that there were 10 primary resections. Three died, giving a mortality of 30 per cent. Two who required further resections are improved. Five are clinically cured but 1 of these had to have more surgery. Thus, complete cure with one operation occurred in 4 only—40 per cent. There were four multiple stage operations—one, a Mikulicz procedure, with no deaths.

There were 4 cases of recurrences. Three occurred following primary resection, and 1 after a preliminary ileosigmoidostomy with later resection. Two of the 4, however, were admitted with abdominal fistulas. All 4 had had a previous appendectomy. Since we have no record of the condition of the ileum at the original operation except in 1 case (Case 4 which has been described more completely), the only inference possible is that examination

of the ileum might have demonstrated an advanced condition of ileitis.

Case 23 is the only case treated medically in our series and is 1 of the few diagnosed without operation. He has been treated for abdominal distress for many years, the diagnosis ranging from appendicitis to gallbladder disease to ulcer. He has had no acute obstructive symptoms, nor has he had episodes of fever, nausea, and vomiting suggesting acute appendicitis. He has had no diarrhea, although his bowels move regularly twice a day without cathartic. At the present time he is in excellent physical condition and has no complaints so long as he stays on his diet. It must be emphasized that at no time has he been seriously ill. He has been advised to have an ileocolostomy by a member of the Mount Sinai group. In our opinion, considering his age and the low-grade activity present, conservation seems indicated. He will, of course, receive periodic checkups.

Summary

A survey of the literature and a critical analysis of 23 cases of regional ileitis from Broome County, New York (Table 2), lead to the following conclusions:

1. The main obstacle to a rational treatment of ileitis in the smaller communities lies in the difficulty of diagnosing the condition prior to operation.

2. Cases diagnosed without operation must of necessity have a condition of advanced pathology causing distortion of the bowel as demonstrated by x-ray examination. In these cases, medical treatment is indicated in those patients whose symptoms are mild and not disabling economically, and in whom the condition is quiescent or clinical improvement is present. This would seem to be indicated more often in persons of middle age, since its diagnosis at that time would, in itself, tend to indicate a long slow course. Medical treatment is also indicated in cases in which the condition of the patient or the extent of the involvement of the bowel forbids surgery.

3. Surgical treatment is indicated in medical cases that show progression as evidenced by physical debility or by signs of obstruction, abscess, or fistula formation.

4. Surgical treatment in acute mild cases found inadvertently at operation without evident obstruction or abscess formation should be restricted to simple exploration. Appendectomy seems safe if desired.

5. Acute surgical cases found inadvertently at operation but presenting signs of severe infection, abscess formation, or obstruc-

tion should be treated for the presenting pathology only. Further surgery may be done when the acute process has subsided. When the microscopic report on an apparent gangrenous or ruptured appendix shows chronic inflammation only, ileitis is to be considered and a careful follow-up should be done.

6 In advanced cases, primary resection gives the best clinical results, but the mortality is prohibitive.

7 Resection in stages gives a much lower mortality and is preferable for the average surgeon. It is especially indicated in cases with fistula formation. Either a preliminary ileotransversecolostomy with section of the ileum or the Mikulicz procedure as advocated by Marshall¹² may be used.

LORD HORDER ON AIR-RAID SHELTERS

In an address to the Royal Society of Arts on "The Modern Troglodyte," Lord Horder, who was appointed by the government to inspect and report on air-raid shelters, said that we heard a lot about foreigners crowding into the shelters, but these folk were under British protection and we must give them security and care for them. That was where we differed from the Nazis. This great and cataclysmal upheaval had brought into the shelters for inspection the squalid conditions of which we said we were ashamed. For many of these citizens what the authorities had now been able to establish represented better and happier conditions than they had before night bombing began. This was an indictment of what had been called "our social system." These folk now enjoyed a communal life, though of a rudimentary sort, which bred a spirit of good temper and dignity, it enabled them to adapt themselves to the nation's exigency and spirit. That it should have needed a war and life under ground for half of the twenty-four hours to achieve a result which was bringing joy to the hearts of social workers was a humiliating thought. To get among the ordinary folk and give them sane, simple, and homely advice was the dream of doctors with any vision for one hundred years. Here was field work of the best kind in preventive medicine to keep the fit fit and to make the near fit fit. He believed that from these severe trials would emerge a group of people better fitted to arrange the pattern of their lives in the better days that all were determined to have in the future.—*J.A.M.A. London letter*

DISQUIETING

There is a "natural reluctance" just now to take issue with the Chief Executive, remarks the *New York Medical Week*, but at the same time the physicians of America cannot close their eyes to a continuing tendency on Mr. Roosevelt's part to entrust medical tasks of the first magnitude to laymen.

"One would imagine that the coordination of 'all health, medical welfare, nutrition and other related fields of activity affecting the national defense' would call for a thoroughly trained physician with broad experience in the fields involved. That there are many such men in private practice and public health work in this country no one can for a moment doubt. Instead Mr. Roosevelt has chosen to entrust this essentially medical task to Federal Security Administrator Paul V. McNutt.

"Among the medical questions over which Mr. McNutt has been given jurisdiction are the medical aspects of the draft, including the rehabilitation of rejected men, civilian and military medical supplies, sanitation, health and medical service in defense industrial sections and mobilization areas, transfer of funds for health and welfare purposes, and correlation of all governmental medical agencies.

"This new assignment gives Mr. McNutt virtually complete control over medical practice as it relates to defense—and what cannot be included in this category? It is disturbing to see these enormous powers lodged in one of the President's political henchmen rather than in a qualified medical man," concludes the *New York Medical Week*.

occur in any intestinal procedure and is one of the reasons for a preliminary short-circuiting as suggested by Colp and Ginzburg.¹⁹

Case 11 was operated on with a diagnosis of malignancy, and primary resection with side-to-side anastomosis was performed. Death occurred during convalescence from embolism. Embolism is a too common occurrence in bowel resections to warrant comment. Again preliminary short-circuiting is suggested as safer.

A résumé of the 22 surgical cases reveals that there were 10 primary resections. Three died, giving a mortality of 30 per cent. Two who required further resections are improved. Five are clinically cured but 1 of these had to have more surgery. Thus, complete cure with one operation occurred in 4 only—40 per cent. There were four multiple stage operations—one, a Mikulicz procedure, with no deaths.

There were 4 cases of recurrences. Three occurred following primary resection, and 1 after a preliminary ileosigmoidostomy with later resection. Two of the 4, however, were admitted with abdominal fistulas. All 4 had had a previous appendectomy. Since we have no record of the condition of the ileum at the original operation except in 1 case (Case 4 which has been described more completely), the only inference possible is that examination

of the ileum might have demonstrated an advanced condition of ileitis.

Case 23 is the only case treated medically in our series and is 1 of the few diagnosed without operation. He has been treated for abdominal distress for many years, the diagnosis ranging from appendicitis to gallbladder disease to ulcer. He has had no acute obstructive symptoms, nor has he had episodes of fever, nausea, and vomiting suggesting acute appendicitis. He has had no diarrhea, although his bowels move regularly twice a day without cathartic. At the present time he is in excellent physical condition and has no complaints so long as he stays on his diet. It must be emphasized that at no time has he been seriously ill. He has been advised to have an ileocolostomy by a member of the Mount Sinai group. In our opinion, considering his age and the low-grade activity present, conservation seems indicated. He will, of course, receive periodic checkups.

Summary

A survey of the literature and a critical analysis of 23 cases of regional ileitis from Broome County, New York (Table 2), lead to the following conclusions:

- 1 The main obstacle to a rational treatment of ileitis in the smaller communities lies in the difficulty of diagnosing the condition prior to operation.

- 2 Cases diagnosed without operation must of necessity have a condition of advanced pathology causing distortion of the bowel as demonstrated by x-ray examination. In these cases, medical treatment is indicated in those patients whose symptoms are mild and not disabling economically, and in whom the condition is quiescent or clinical improvement is present. This would seem to be indicated more often in persons of middle age, since its diagnosis at that time would, in itself, tend to indicate a long slow course. Medical treatment is also indicated in cases in which the condition of the patient or the extent of the involvement of the bowel forbids surgery.

- 3 Surgical treatment is indicated in medical cases that show progression as evidenced by physical debility or by signs of obstruction, abscess, or fistula formation.

- 4 Surgical treatment in acute mild cases found inadvertently at operation without evident obstruction or abscess formation should be restricted to simple exploration. Appendectomy seems safe if desired.

- 5 Acute surgical cases found inadvertently at operation but presenting signs of severe infection, abscess formation, or obstruct-

tion should be treated for the presenting pathology only. Further surgery may be done when the acute process has subsided. When the microscopic report on an apparent gangrenous or ruptured appendix shows chronic inflammation only, ileitis is to be considered and a careful follow-up should be done.

6 In advanced cases, primary resection gives the best clinical results, but the mortality is prohibitive.

7 Resection in stages gives a much lower mortality and is preferable for the average surgeon. It is especially indicated in cases with fistula formation. Either a preliminary ileotransversecolostomy with section of the ileum or the Mikulicz procedure as advocated by Marshall¹³ may be used.

"This new assignment gives Mr. McNutt virtually complete control over medical practice as it relates to defense—and what cannot be included in this category? It is disturbing to see these enormous powers lodged in one of the President's political henchmen rather than in a qualified medical man," concludes the *New York Medical Week*.

STEVENS-JOHNSON DISEASE WITH COMPLETE VISUAL RECOVERY

ISADORE GIVNER, M D , F A C S , and HARRY AGELOFF, M D , New York City

IN DEALING with a disease that has resulted invariably in ocular impairment varying from reduced vision to complete loss of the eyes, any information that may be of value in changing these statistics should be welcome. The importance of the care of the eyes in this disease has been mentioned by Wheeler,¹ but it can bear repetition, for in this recognition lies the first step in the eradication of the sequelae which as a rule have had their forerunners, purulent conjunctivitis and corneal ulcerations, develop before appropriate measures have been introduced.

Von Hebra² in 1866 gave the name of erythema multiforme exudativum to a group of polymorphous erythemas which he considered due to a systemic invasion of some unknown factor. He stated that mucous membranes may be involved but did not stress the occurrence of conjunctivitis of a serious type. This form was recognized by Mracek³ and Crocker,⁴ the latter noting that the conjunctiva may be the first part affected.

If one excludes the streptococcic pseudomembranous conjunctivitis, which should not be classed with this group of cases, nothing of importance was said of this disease until Stevens and Johnson⁵ in 1922 described the cases of 2 children in whom ulcers appeared in the cornea, with resultant scarring in 1 and a bilateral suppurative keratitis with perforation and purulent ophthalmia in the other. The latter resulted in total blindness. They felt they had described a new entity of high fever, a generalized eruption of buccal mucous membrane and eye involvement.

In 1930 Wheeler reported a case of this type which resulted in loss of vision in both eyes.

Bailey⁶ in 1931 expressed the belief that the entity described by Stevens and Johnson were forms of erythema multiforme with more eye involvement than that which generally occurs. He likewise reported 3 cases, all of which had some loss of vision. In 1935 Gnanades⁷ added another case to the literature, noting 5 per cent monocytes in the blood and culturing *Staphylococcus aureus* from both conjunctivas and vesicles of the skin, as well as from one eye enucleated for panophthalmitis.

To these contributions we should like to add 2 cases.

Case Reports

Case 1—E. W., a man aged 23, clerk, was admitted to Post-Graduate Hospital on November 9, 1939, with a history that he had been in good health until November 6 when he noticed a dryness of his eyes accompanied by a smarting sensation. He felt well on November 7 but that night was awakened by a painful blister on the roof of his mouth. The next day, November 8, he was feverish, and the blister had spread over his tongue and throughout his mouth and throat with resultant dysphagia. A physician gave him 60 grains of sulfanilamide. He developed photophobia and headache, and a rash appeared over his arms, legs, face, and neck.

His past history disclosed anterior poliomyelitis when a child, but with no sequelae.

Examination of his eyes disclosed a catarrhal conjunctivitis, cultures from which showed a *Staph. aureus*, nonhemolytic in type but which fermented mannitol with production of acid. His corneas were clear. There was drooling from his mouth with ulceration and crusted vesicular lesions in both nasal passages, and generalized over the mucous membrane of his throat and oral cavity was a sloughing membrane.

His face, forearms, extensor surfaces of arms and legs, chest, and back were covered with round and ovoid macules which faded on pressure. His temperature was 104° F. An infusion of 700 cc. of 10 per cent dextrose was given by his attending physician, Dr. Maurice Bruger, through whose courtesy we are presenting this case.

The next day the macules over his body had become confluent and his temperature was 103° F.

On November 11 a smear from the conjunctiva stained with Wright's stain showed 20 per cent monocytes, the same as that found in his blood smear at that time.

On November 14 the lesion started to dry but the conjunctivas began to show a filmy exudate over both eyes occluding the vision. The temperature was 101° F. (Fig. 1).

On November 15 a marked pseudomembrane had formed. On entering the room one saw a patient whose lids were held tight with a membrane bulging forward in the palpebral aperture through which, deep below, were seen the corneas. The relationship of the cornea to the membrane suggested that seen when one views a fetus through an amniotic sac. This membrane was removed sufficiently to separate the lids and get a better view of the corneas. Another culture was taken, and *Staph. aureus* was again found. The cornea was not involved, a pseudomembrane covered over the palpebral conjunctiva completely. This could be peeled

FIG 1 Crusted vesicular lesions of lips and generalized eruption

off and only here and there leave a bleeding surface. Cod-liver oil was instilled into the conjunctival sac (Fig 2).

On November 16 a new crop of vesicles appeared over both hands. Cultures of these vesicles and stains with victoria blue for elementary bodies were negative. Cultures of the conjunctiva on the chorio-allantoic membrane of a chick were negative for virus or any other organisms.

On November 21 the patient vomited several ounces of blood, probably from ulceration in the esophagus. The eyes showed improvement under a treatment that consisted of cleaning of the eyes twice a day and instillation of cod-liver oil.

On December 1 no membrane was left on the conjunctiva. Blood counts and blood chemistry showed nothing of importance at any time, except a high monocyte count early in the disease. Wassermann was negative, blood culture was negative, and tests for lead and arsenic excretion were normal.

The patient made an uneventful recovery with no corneal involvement occurring at any time. His vision is 20/20 in each eye. There remains, however, a small symblepharon from the outer temporal portion of the right palpebral conjunctiva of the lower lid to the bulbar conjunctiva. This does not interfere with ocular motility. At the time of writing the nails of the fingers of both hands are half way off, with new nails growing in from below (Fig 3).

Case 2. A 4-year-old white girl was first seen at the Lincoln Hospital on July 4, 1939. Her

FIG 2 Pseudo-membranous conjunctivitis

FIG 3 Complete recovery with clear corneas

family history was irrelevant and development was normal. She had had measles at 3 years of age but no other childhood diseases. She complained of frequent sore throat and colds, especially in winter. For the two months previous to admission until three weeks before, she had had a bilateral purulent otitis media. Otherwise she was quite well until three days before admission. The evening before the onset of illness the patient had had a haircut. The barber had used a hair lotion and later that evening the mother had put some "Larkspur" on her hair. She appeared cranky and feverish that evening. The next morning her face was diffusely red-

FIG 4 Confluent erythematous maculopapular eruption

dened and the conjunctivas were injected. During that day the erythema spread to the neck and shoulders and during the next two days included the rest of the body. On the day before admission large blisters formed on her face, arms, and upper part of the body. In some places the blisters ruptured and the dead skin had peeled, leaving a raw cutaneous surface. She complained of intense pain with micturition. The vaginal mucous membranes appeared involved. The patient had a fever but no chills.

Outside of the "Larkspur" and an unknown hair lotion, there was no other medication used, either externally or internally.

Physical Examination The child was acutely ill and obviously in gross distress. The skin of the entire body, exclusive of the scalp, was covered with confluent erythematous maculopapular eruption (Figs 4 and 5). The upper extremities, face, neck, and chest anteriorly were covered with bullous vesicles, ranging in size from a pin-head to large, confluent bullae about 6 inches long and 3 inches wide. Some of the bullae had ruptured, a thin, watery fluid had exuded, and the skin had peeled away, leaving a raw, red, oozing surface. The posterior thorax was the least involved. **Head**—The scalp was surprisingly free of any lesions, the hair border acting as a line of demarcation. **Eyes**—The lids were glued together by a thick, yellow purulent exudate. The eyes could be opened only with difficulty. **Ears**—The skin was entirely off bilaterally. The right drum was thick and scarred, the left drum was dull and had no light reflex. **Nose**—Mucoid secretion obstructed respiration. **Mouth**—The lips were raw and covered with clotted blood, the tongue was heavily coated. The mucous membranes contained large, white ulcerated patches throughout. The tonsils were not involved. The heart and lungs revealed no

abnormalities. The abdomen was negative with no palpable organs, and the vagina revealed inflamed mucous membranes. The balance of the physical examination was negative.

Treatment She was placed on a course of neoprontosil, frequent boric acid eye washes, and gentian violet application to the skin lesions after daily starch baths. Because of the painful mouth lesions preventing adequate food and fluid intake, a continuous infusion for three days was given to supply fluids. Metaphen 1, 2,500 three times a day was put into the eyes, and later butyn metaphen ointment was substituted. Vitamins B and C were provided in tablet form, and sedatives were given liberally.

Course **Eyes**—In two days she was able to open her eyes. It was then observed that the corneas were intact. Seven days after onset of illness the discharge noticeably decreased. Vision was intact at all times. Thirteen days after onset a cicatricial ectropion developed, due to scab formation under both lower lids. The corneas were thus partially exposed during sleep, and it was feared that corneal scarring might occur. The scabs were therefore softened and removed in a few days with almost immediate restoration of the eyelids to normal by the tenth day. By the eighteenth day the eyes appeared normal except for the subjective symptom of photophobia—relieved by smoked glasses.

Skin—The bullae were confined to the upper part of the body. These, and other desquamated areas responded well to gentian violet and starch baths. By the eleventh day the skin lesions had assumed a brownish tinge and scaly appearance and the denuded areas were dry. The face was covered with a hard, dry crust. The mouth and lips bled easily. The scalp was not involved primarily, but a small lesion the size of a quarter was noted over the occiput on the eighteenth day. This was believed to have been caused by pressure. It was unlike the other skin lesions. About this time (the eighteenth day) the lesions began to heal almost completely, and three-fourths of the scabs had fallen off or had been removed. She was on the road to recovery.

On the eighteenth day small nontender vesicles appeared on the palms of the hands, and in a few days the superficial layer of skin had come off. The same thing occurred with the soles of the feet a few days later. No scars remained.

Temperature—On admission the temperature was 102.2 F. In three days it had reached a peak of 104.8 F and then slowly dropped to normal by the fourteenth day of her illness and continued so until discharge.

Laboratory The urine test showed a trace of albumin with many red blood cells, but the specimen was not catheterized and the vaginal lesions were severe, so that this was believed to be contaminated. Later the urine cleared. The blood test revealed hemoglobin, 11.2 Gm., red blood count, 3,870,000, white blood count,

8,750, lymphocytes, 43 per cent, polymorphonuclears, 53 per cent, and monocytes, 4 per cent. Five days later the white blood count was 14,600, lymphocytes, 40 per cent, polymorphonuclears, 56 per cent, and monocytes, 3 per cent. On the twentieth day of her illness the blood test showed white blood count, 20,400, polymorphonuclears, 75 per cent, lymphocytes, 20 per cent, and monocytes, 5 per cent. The Wassermann, urea nitrogen, and blood sugar were negative. A mouth culture yielded *Staph. aureus*, a conjunctival culture yielded *Staph. aureus*, *Bacillus proteus*, and *Staph. albus*. Stools were positive for blood (guaiac test).

Discussion

We have since seen a third case which, however, had only a catarrhal conjunctivitis with no membrane formation in the eye. A culture taken from a vesicle of the skin of this case was injected into the anterior chamber of a rabbit and produced a panophthalmia in four days. *Staph. aureus* was the offending organism.

These last 3 cases all had sulfanilamide at some time during their course. With perfect recovery as far as absence of corneal involvement is concerned, one wonders if there could be any relationship of the good recovery to the administration of the sulfanilamide. Herrell and Brown⁸ have shown that sulfanilamide *in vitro* will inhibit the growth of *Staph. aureus* tenfold.

It is interesting that all the cases of Stevens-Johnson disease in which mention was made of the bacteriologic findings in the conjunctiva showed the *Staph. aureus* either alone or with other organisms. Whereas it is true that 68 per cent of normal individuals will show staphylococcus in their conjunctiva on culture, usually the albus, the constant finding of this organism in these cases seems to us to be significant.

The cause of the erythema multiforme so reduced the vitality of the tissue to allow the organisms to better attack the eye and skin. From the culture taken from Case 1 and injected into the anterior chamber of a rabbit a panophthalmia resulted, no effect was noticed on either conjunctival instillation or subconjunctival injection.

At the present time, studies are being made with sulfathiazole, first, to see if it is secreted into the anterior chamber and, second, to see if it will prevent staphylococcal infections of the globe. Experiments *in vitro* show it to be ten times as effective against *Staph. aureus* as sulfanilamide.

FIG 5 Appearance with gentian violet application

Whereas it is impossible to be sure on only 2 cases that the care and handling had anything to do with the favorable result, it would seem that daily observation of the eyes before complications develop, with the thought in mind of preventing the collection of pus and giving consideration to the use of some agent that will act bacteriostatically in regard to the staphylococcus, seems at the present time the best way to help prevent the usual fatal ocular outcome.

Case Reports

BRUCELLOSIS WITH POSITIVE BLOOD CULTURES AND NEGATIVE ALLERGIC SKIN TESTS

Report of Two Cases

M L SINGEWALD, M D , Cooperstown, New York

THE following 2 cases had positive blood cultures for *Brucella abortus*, and positive agglutination reactions. The allergic skin tests with Brucellergen (Huddleson) showed erythematous reactions at twenty-four hours with negative readings at forty-eight hours. These skin reactions would usually be considered as negative.

Case Reports

Case 1—P, a girl, aged 7, who had consumed raw milk for some time, was admitted to the Pediatric Service of the Mary Imogene Bassett Hospital on October 13, 1939, having been taken ill seven days before with chilly sensations, general malaise with flushing, nausea, and vomiting, and a fever fluctuating between 102 and 105 F. On admission the temperature was 103 F, pulse, 120, respirations, 20, blood pressure, 110/80. She was a young girl who was warm and flushed and in no acute distress. On general physical examination she seemed normal except for an enlarged, palpable spleen. The heart was not enlarged and the rhythm was regular, but there was a soft blowing, systolic murmur at the apex.

The blood count showed hemoglobin, 91 per cent, red blood cells, 4,750,000, white blood cells 4,700, polymorphonuclears, 68 per cent, small lymphocytes, 25 per cent, large lymphocytes, 4 per cent, monocytes, 5 per cent, smear, normal. The Wassermann reaction was negative in both antigens. The Widal and heterophil antibody agglutinations were negative. The stool culture was negative for organisms of the enteric disease group. The patient's serum showed agglutination with *Br. abortus* in dilution of 1 to 40. The allergic skin test with Brucellergen (Huddleson) at twenty-four hours, showed an erythema of 2.5 cm in diameter which was only slightly elevated, and the test was negative after forty-eight hours (October 16, 1939). The blood culture grew out *Br. abortus* on hacto-tryptose agar media under increased CO₂ tension. The opsonocytophagic test was not performed.

In the hospital the patient continued to run a swinging temperature but otherwise felt quite comfortable and had no complaints. She was started on sulfanilamide (October 21, 1939) without any striking results. The white blood count dropped to 2,900 with 48 per cent polymorphonuclears, so the sulfanilamide was stopped after the patient had received 15.8 Gm. The temperature slowly dropped to normal and the patient was discharged on October 31, 1939. The agglutination titer with *Br. abortus* rose to 1 to 320 (October 30, 1939) and, when the patient was

next seen in the outpatient department on November 15, 1939, she was apparently well and the agglutination reaction was negative. This case is reported through the courtesy of Dr. Marjone F. Murray.

Case 2—K, C, a schoolboy, aged 14, who had consumed raw milk for a number of years was admitted to the Medical Service of the Mary Imogene Bassett Hospital on December 20, 1939. About one and one-half weeks prior to entry he contracted a head cold, which persisted, and three days before admission he was suddenly taken ill with nausea, vomiting, and headache. The next day there was some substernal discomfort. On admission, the temperature was 104 F, pulse, 110, respirations, 28, blood pressure, 110/58. The patient was a slight young lad, flushed and toxic. The general physical examination revealed signs of consolidation over the right lower lung posteriorly. The spleen was not palpable.

The blood count showed hemoglobin 78 per cent, red blood cells, 4,680,000, white blood cells 14,250, with 93 per cent polymorphonuclears. The sputum was rusty and tenacious and a *Diplococcus pneumoniae* type I was identified by the Neufeld reaction. This was confirmed by culture and inoculation of a mouse. The Wassermann reaction was negative in both antigens. The patient's serum agglutinated *Br. abortus* in dilution of 1 to 320. The allergic skin test with Brucellergen (Huddleson) showed approximately 15-mm erythema at twenty-four hours and was negative at forty-eight hours (December 30, 1939). The opsonocytophagic test with *Br. abortus* showed slight phagocytosis (December 29, 1939). The blood culture grew out *Br. abortus* in beef infusion broth under increased CO₂ tension.

On the night of admission the patient was given 200,000 units of New York State antipneumococcus serum, type I, intravenously. The temperature gradually came down to normal in the course of the next few days, and the patient was greatly improved. On the tenth hospital day there was a slight elevation of temperature, and it was discovered that the patient had a pleural effusion on the right. Thoracentesis revealed cloudy yellow fluid with the characteristics of an exudate, sterile on culture. Symptomatically, this complication did not bother the patient and he proceeded to improve.

A repeat of the Brucellergen skin test (January 8, 1940) showed approximately 15-mm erythema at twenty-four hours and a 4-mm papule, 20-mm erythema at forty-eight hours.

The agglutination titer with *Br. abortus* rose to 1 to 640 on January 5, 1940, and another blood culture taken on January 8, 1940, showed no growth after fourteen days.

The patient was discharged on January 13, 1940, feeling quite well, with a normal temperature. He was seen in the outpatient department on January 22, 1940, his temperature having been essentially normal for eight days. His blood serum agglutinated *Br abortus* in a dilution of 1 to 320. This case is reported through the courtesy of Dr. George M. Mackenzie.

BENIGN INTRATHORACIC GOITER WITH RECURRING PLEURAL EFFUSION

Report of a Case

STUART E. KROHN, M.D., Utica, New York

DURING recent years considerable attention has been given to the importance of the recognition of intrathoracic goiter.¹⁻³ The patient whose clinical record is here presented manifested the unique complication of a recurring pleural effusion during the latter several years of an eighteen years' existence of an intrathoracic goiter. Outside of Schultze's report of a case of intrathoracic goiter complicated with a chylothorax, no other description of a pleural effusion complicating a benign colloid intrathoracic goiter was found in a survey of the literature. Although this case was presented for diagnosis at a hospital conference,¹⁰ it appears to be of sufficient interest to warrant its presentation in the form of a complete case report.

Case Report

On April 30, 1937, a 61-year-old Jewish woman consulted me because of a dry hacking cough, shortness of breath, a sense of oppression in the upper part of the chest, and choking spells. Although these symptoms were mainly complained of for the two and a half years before this date, the patient's present illness really dated back to August, 1920, at which time she first experienced the above-mentioned symptoms. A few months after this she entered the Mount Sinai Hospital in New York City where it was noted that she had an encapsulated mass the size of a plum in left lobe of the thyroid. Roentgenologic examination revealed a large mediastinal tumor not having any definite connection with the former mass in the thyroid. An operation on the mediastinal tumor was advised, but the patient refused.

From March, 1921, to June, 1923, the patient received a series of seven radium treatments applied to the superior mediastinum. Remarkable symptomatic improvement followed. She gained about 20 pounds in weight and for the following twelve years she felt extremely well. However, in March, 1935, following a respiratory infection, a right-sided pleural effusion occurred. From this time on she began to suffer from symptoms of mediastinal compression. Thoracentesis gave her relief, the first one being performed a month after onset of the effusion. At this time 1,400 cc of a clear yellow fluid, having all the characteristics of a transudate, was obtained from the right side of the chest. From this time

These cases illustrate that the allergic skin test may be negative at forty-eight hours, even though active infection is present, and that the twenty-four-hour reactions, even though slight, may have been of some significance. In Case 2 there is the possibility that the development of skin sensitivity may have been retarded by the presence of the pneumococcal lobar pneumonia.

until her death on March 6, 1938, a thoracentesis was performed every month or two for relief of respiratory distress.

The family, marital, personal, and past histories revealed nothing of importance or pertinent to the present condition.

Physical Examination.—The patient was well developed and nourished, weight, 115 pounds, height, 5 feet. She was in considerable respiratory distress. Her pulse was 96 and regular. Her temperature was 99 F and blood pressure 140/90. A moderate degree of cyanosis was present in lips and fingernail regions. Telangiectatic lesions, presumably from radium irradiations, were scattered over the upper anterior part of the chest. A marked and advanced dilated and anastomosing network of veins was present over the superior mediastinum, and this extended into the right axillary region and down the chest nearly to the right costal margin. There was a boggy thickening of the skin and subcutaneous tissues in the region of the thyroid gland, but no masses or enlargements could be made out. No thyroid gland was felt in the suprasternal notch. Increased width of percussion dullness was noted in the superior mediastinum. Her heart appeared to be of normal size and was not displaced to the left, and outside of a systolic murmur heard at the apex nothing unusual was found here. Signs of fluid were present in the lower third of the right side of the chest posteriorly. The liver edge was felt at the level of the umbilicus, and it was smooth and nontender. The upper limits of the liver merged with the fluid dullness. Rectal, pelvic, and sigmoidoscopic examinations revealed no abnormal findings. Complete laboratory investigations were all in the normal range, this included studies on urine, complete blood counts, sedimentation rates, and serologic tests for syphilis. The fluid obtained from another thoracentesis was carefully studied, and histologic examination of the sediment and guinea-pig inoculation for tuberculosis were negative. Roentgenologic studies again showed the same character of a mediastinal tumor as seen previously. No evidence of metastatic lesions was seen in the chest after withdrawal of the fluid. Roentgenologic investigation of the gastrointestinal and genitourinary tracts shed no light on the diagnostic problem.

Further Course.—In October, 1937, the patient entered the Baker Memorial Hospital in Boston

FIG 1 Shows enlarged mediastinal shadow, fluid in the right side of the chest, and displacement of trachea to right and esophagus to left

FIG 2 Photograph of anterior view of necropsy specimen of the intrathoracic goiter in relation to the lungs and large vessels at the base of the heart

Intensive studies and careful observations here failed to establish a definite diagnosis, but the consultants who examined her felt that a substernal thyroid was a likely diagnosis, although a malignant degeneration of the gland could not be ruled out. Fig 1 is from a roentgenogram taken at this time, and shows the trachea somewhat displaced to the right and the esophagus to the left by the mediastinal mass. A moderate amount of fluid is seen in the right side of the chest, although at other times fluid was seen to extend up to level of clavicle. An operation was advised but was again refused, and on a second admission to this same institution the patient died suddenly on March 6, 1938. Permission for an autopsy limited to the chest was obtained.

Report of Main Findings at Autopsy (under supervision of Dr. Tracy B. Mallory) — "*Pleural cavities* The right side of the chest contains about 3 l. of clear straw colored fluid, and the left about 800 cc of similar fluid.

"*Thyroid gland* (see Fig 2) The thyroid is very much enlarged forming a mass extending from the inferior border of the thyroid cartilage for a distance of 13 cm. down behind the sternum to the arch of the aorta. The mass measures 8.5 cm. in width and 3 cm. in thickness. It is composed of four large nodules, one of which lies entirely within the mediastinum and measures 5 by 5 by 2 cm. This nodule compresses the left and right innominate veins and displaces the innominate artery and left common carotid laterally. This tumor mass is moderately firm but not hard in consistency. It is completely encapsulated and shows off the surrounding structures with ease. The mass has a varying cut surface. In some areas it is composed of a very homogeneous tissue dotted with tiny flecks of colloid and in others it is composed of fairly necrotic material, containing large areas of colloid and numerous foci of calcification."

Microscopic examination of thyroid gland "Several sections through the thyroid show different microscopic pictures. In one area the acini are markedly dilated, have very low epithelium, and are filled with colloid. In these foci, the stroma is abundant, dense, and hyaline. There are no lymphoid foci or any evidence of hyperplasia malignancy."

Anatomic Diagnoses — "Substernal thyroid, struma nodosa micro et macro-folliculare with compression of the right innominate vein, hydrothorax, bilateral, pulmonary atelectasis, right, pulmonary emphysema, slight, right, pulmonary edema, left, pleuritis, chronic fibrous, bilateral."

Comment

Pressure on such important veins as the innominates certainly seems a likely reason for the recurring pleural effusion. However, other unusual features must have been in operation as, hydrothorax has not been reported in other cases of intrathoracic goiter in which probably similar degrees of pressure on vessels had been present. The many years of existence of this mediastinal mass in this patient undoubtedly subjected the venous collateral system seen on the chest wall to a severe strain, and the respiratory infection was a sufficient additional factor to usher in the effusion.

Summary

A report of a case of a patient with recurrent pleural effusion complicating a benign intrathoracic goiter is presented. The salient features of the eighteen-year course are reviewed, and emphasis is placed upon the interest and rarity of this complication.

I wish to express my indebtedness for the permission to use hospital records and other valuable data concerned with this report to Drs. Bernard M. Jacobson and Tracy B. Mallory, both of the Massachusetts General Hospital, Boston, and to Drs. L. Whittington Gorham and Thomas Ordway, both of the Albany City Hospital, Albany, New York. In addition, I am grateful

to the various hospitals that allowed me free use of their records

PNEUMOCOCCIC MENINGITIS, TYPE XIII, COMPLICATING FRACTURE OF THE SKULL

Recovery Using Sulfapyridine

WALTER D. LUDLUM, JR., M.D., and CARL A. PETERSON, M.D., New York City

C. M., a well-developed and well-nourished married laborer, aged 40, was carried unconscious into the Reconstruction Hospital, December 27, 1938, following a fall from a truck. He remained unconscious for about fifteen minutes.

He bled profusely from the nostrils. The mouth was filled with a frothy, blood-stained fluid. He was cyanosed and breathed with difficulty. An ecchymosis and swelling had completely closed the right eye. There was a superficial abrasion of the right temporoparietal region.

The temperature on admission was 99 F., pulse, 120, respirations, 18, blood pressure, 130/70. The pupils were equal and slightly dilated and they reacted sluggishly. Knee jerks and abdominal and cremasteric reflexes were absent. The Babinski sign was present on the right. An x-ray showed a fracture of the right parietal bone which extended into the base of the skull.

The patient was rational and cooperative during the first day after injury. Neurologic examination revealed no localizing signs of intracranial injury, no evidence of increased intracranial pressure, nor any evidence of meningeal irritation. Spinal puncture revealed a faintly bloody fluid under normal pressure.

Thirty-six hours following injury, the patient became semiconscious and delirious. In twelve hours his temperature rose from 99.8 to 105.6 F., with an increase in the pulse to 134 and respirations to 34. Nuchal rigidity, Brudzinski, and Kernig signs were positive. Spinal fluid was xanthochromic and somewhat cloudy and was under a pressure of 35 mm. of mercury. A

cell count showed 2,100 red blood cells and 1,590 white blood cells per cubic millimeter of spinal fluid. A smear failed to reveal organisms.

Eighty grains of sulfanilamide were administered during the succeeding twenty-four hours without appreciable effect (Chart I).

Spinal fluid culture (after twenty-four hours' incubation) revealed pneumococci of type XIII. On ascertaining the type of the infection, sulfapyridine (then available only for experimental purposes) was substituted for the sulfanilamide. An initial dose of 5 Gm. of sulfapyridine was given by mouth, followed by 2 Gm. every four hours for a period of forty-eight hours. Signs of the meningeal infection regressed, and the temperature dropped from 104.6 to 101.8 F. in twenty-four hours.

Seventy-two hours following the administration of the sulfapyridine, the temperature and pulse had returned to normal, and no signs of the meningitis remained. The cell count of the spinal fluid dropped to 260 white blood cells per cubic millimeter. A persistent nausea and occasional vomiting interfered with an adequate intake of the sulfapyridine, and only 9 Gm. were retained in the subsequent forty-eight hours. The concentration of the drug fell from 19.7 to 4.3 mg. per hundred cubic centimeters in the blood, and from 8.8 to 3.5 mg. per hundred cubic centimeters in the spinal fluid (Table I).

On the sixth day postinjury, the temperature climbed abruptly from normal to 104.8 F. The patient became semiconscious and delirious, and nuchal rigidity with other signs of meningeal inflammation reappeared. The spinal fluid white cell count rose to 1,310 per cubic millimeter. Twenty-six grams of sulfapyridine were given in the following seventy-two hours. The patient again became rational, the temperature returned to normal, and the signs of the meningitis subsided.

From the service of Dr. H. H. Ratter, Reconstruction Hospital Unit of the New York Post-Graduate Medical School and Hospital, Columbia University.

TABLE 1

Date	Cells per Cu Mm	Initial Pressure (Mm)	Dose Sulfapyridine (Grams)	Concentration of Sulfapyridine in Blood, Mg per 100 Cm.	Concentration of Sulfapyridine in Spinal Fluid, Mg per 100 Cm.
12/29	3,700	35			
12/30	9,000? (clumps)	10	7		
12/31		10	12	14.5	9.5

1/21			0		
1/22			5		
1/23			3		
1/24			3		

The sulfapyridine was continued for three days more. The culture of the spinal fluid was negative on these three successive days. Repeated blood cultures were also negative.

The patient complained, however, of pain and discomfort in the right side of the chest. There was an evening rise in temperature. Signs of bronchopneumonia with pleurisy involving the right side of the chest were found, and these findings were confirmed by x-ray. Sulfapyridine was again administered in comparatively small doses of 4 Gm. in twenty-four hours for four days. The temperature returned to normal and the chest signs disappeared.

The patient was discharged forty-two days following admission to the hospital. The only residual was a complete deafness of the right ear. It is difficult to say whether this deafness was the result of a lesion of the eighth cranial nerve due to a fracture of the skull, the result of

the meningitis, or the result of the sulfapyridine. He returned to his regular work six months after the accident.

Conclusions

A case of type XIII pneumococcal meningitis complicating a fracture of the skull and treated by sulfapyridine with recovery is reported.

The type XIII pneumococcal meningitis has not been reported in the literature previously.

Consultations by Dr. Henry H. Ritter, Dr. Jesse Godfrey M. Bullowa, Dr. Abbott W. Allen, and Dr. Morris Rosenthal are gratefully acknowledged.

Without cooperation of the people, a doctor can no more prevent tuberculosis than he can

prevent accidental drowning—U S Pub Health Serv Rept, December, 1940

Therapeutics

CONFERENCES ON THERAPY

THESE are stenographic reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments and institutions. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors. The next report will appear in the October 1 issue and will concern "Management of Constipation."

General Management of a Seriously Ill Patient

DR EUGENE F. DuBOIS. The subject to be discussed is the care of the seriously ill patient suffering from a febrile disease.

In introducing this subject I should like to remind you of some of the aspects of pathologic physiology in fevers. First, we have the specific manifestations for each different disease. I shall not consider them but take up the nonspecific manifestations that are common to most febrile diseases.

There are many balances that are upset in fever. The most striking is, perhaps, the balance of temperature regulation, the temperature-regulating center being set at a higher level and more variable in its setting so that the temperature usually goes up and down at different periods of the day. In few fevers is a fairly constant level maintained.

Heat production, one side of the balance, is usually increased in proportion to the fever. Heat loss is also increased but is variable. Sudden increases in heat production are usually accomplished by chills. Therefore, a chill is an evidence of a sudden rise in the setting of the temperature-regulating center. Sudden losses of heat when the temperature-regulating center is lowered are usually accomplished by sweating. Those are the emergency mechanisms. Smaller variations can be taken care of by changes in the circulation of blood to the skin and minor adjustments of vaporization.

The caloric balance is grossly upset. The caloric output is increased, and the caloric intake is almost invariably diminished because of lack of appetite. The protein balance is upset the same way, in that the protein loss by protein destruction is increased, probably as the result of toxins in the disease. The protein intake is greatly diminished, the carbohydrate balance is upset. In a similar way the carbohydrate stores in the liver are diminished.

Perhaps most important clinically is the

upset in water balance. The output of water is increased through the higher skin temperature and increased respiration. The water intake is greatly diminished, the biggest source of diminution being the lack of solid food which is our main source of water.

Recently, we have been realizing the importance of the upset of the vitamin balance. It looks as if the demand for vitamins might be higher in disease. Their intake is greatly diminished not only by the diminution in the food, but also there may be changes in the absorption of the vitamins, especially in diarrheal diseases, and perhaps there is also an increased rate of destruction.

The mineral balance is upset and perhaps we have not paid enough attention to the changes in sodium chloride, that is, to the diminished intake due to lack of food.

Now, apart from these upsets in balances we have to remember that the tissues in the body may be damaged by the toxins of the disease. The therapeutic measures employed to meet these changes will be discussed by Dr. Guion.

DR CONNIE M. GUION. What I have to say is chiefly concerned with the practical side of taking care of a very sick patient.

The first step to be considered in taking care of any sick person is to try to find out with what type of man you are dealing, to try to learn his likes and dislikes and his idiosyncrasies, and then to fit the methods of treatment into that patient's personality. In the light of this information I explain to a patient, as fully as seems desirable, the nature of his disease, the length of time that I expect him to be ill, and the plan of treatment I have formulated. It is only by such a method that one can obtain the confidence and cooperation of the sick person. I think we do not realize how much sick people worry about how long they are going to be sick and how sick they are going to be.

Another important preliminary step is the choice of a nurse, because I take it for granted this seriously ill patient will have to have one I select my nurses as carefully as I do my drugs. A sick patient does not wish to hear chatter or a discussion of the nurse's or doctor's personal affairs. They do not like bustle, and they do not like continual treatment. Patients, in the hospital especially, are worn out by the end of the day, and one of the doctor's chief functions is to plan a regimen assuring the patient definite rest—rest from his family, from his friends, and from too much care.

The care of the body in general is important. If a patient is not physically comfortable, he does not get well so fast as he does when he has no physical discomforts.

It is not essential to bathe the entire patient at one time, how much of the patient is bathed must be limited by his reaction to it. Alcohol is often used after a patient is bathed. Cold alcohol should never be dashed on the skin. The alcohol can be set in warm water and brought to body temperature before it is used. After its application it should be rubbed dry so that the patient will have the benefit of the friction to the skin, which is an important part of the bathing.

The type of alcohol to be used is also a problem. You can secure medicated alcohol on the market. Most of it has a vile odor because it is medicated with formaldehyde or other disagreeable agents. I usually order a 50 per cent alcohol without any type of perfume, because sick people get tired of smelling any one odor.

The treatment of sweating is another problem. Dr DuBois has spoken of this. Patients who sweat continually should have a bath every four to six hours and then the skin should be rubbed with 95 per cent alcohol. This decreases the amount of sweating, improves the state of the skin, and increases the peripheral circulation. After a patient has been rubbed dry, it is a good idea to give a massage with either olive oil or with liquid petrolatum. It improves the quality of the skin and prevents it from becoming dry after the use of the alcohol.

Patients who have periodic sweats, causing the night clothes and the bed to become wet, should not have their clothes changed while they are still in a profuse perspiration. If they are extremely uncomfortable when the shirt is wet, we should wait until we are sure the bout of perspiration is over, then give a

warm bath, followed by a massage with 5 per cent alcohol and a change into a warm shirt and bed clothes.

The matter of draw sheets and rubber sheets I think is important. A rubber sheet makes a patient sweat much more than you realize and, if you have ever lain on a rubber sheet very long, you will know it is extremely uncomfortable. If a patient is not incontinent, I think a rubber sheet, except in those hospitals where we have to follow routine, is usually inexcusable. Draw sheets are often placed too low in the bed and, naturally, as the patient lies on the bed the draw sheet is drawn down. It is important to see that it is applied high enough so that it does not become rumpled right under the patient's buttocks.

False modesty often prevents proper cleansing of the genitalia, especially in women. Here there may be a vaginal discharge, and it is important to give a woman a douche if she has a discharge. Many times the peculiar odor which is detected when the bed clothes are thrown back is due not to sweating but to unclean genitalia.

The care of the mouth is difficult in extremely ill patients. To use a toothbrush is often impossible. I find that one of the easiest ways to cleanse a patient's mouth is to use a syringe—Becton Dickinson's Asepto No 2082. With it you can force the water, or whatever cleaning material you are using, through the teeth. Then I use a swab or toothpick to remove any sordes or other material from the gums and between the teeth. A mixture of equal parts of a 3 per cent solution of hydrogen peroxide and 3 per cent solution of boric acid forms a good mouth wash. It cleanses between the teeth and the tongue. This is much more pleasant than having the tongue scraped.

If there is any soreness in the mouth, I use a combination of glycerin and phenol in boric acid as in this formula.

R_x

Phenol 5 per cent	
Glycerin aa	30 00
Boric acid solution 3 per cent	
q s ad	240 00

This is a pleasant tasting preparation and is also slightly anesthetic.

Many things can be done to prevent the mouth and the tongue from becoming dry. One of the simplest measures is to use a cheesecloth mask over the mouth, keeping it moist by dropping water on it. Also, the

tongue can be kept moist by the application of a mixture of strained lemon juice, glycerin, and liquid petrolatum in equal parts. The cleansing of the nose and throat will often relieve mouth breathing and coughing. Albolene should be instilled into the nose, a little at a time. The patient then holds his head down and blows his nose gently. A tampon of argyrol is effective in relieving congestion. Often the pharynx is red, glazed, and streaked by a postnasal discharge. This may be the cause of a great deal of coughing and hacking, which can be relieved by gargling with bicarbonate of soda (one-half teaspoonful to the glass of hot water) or with the old Manhattan gargle.

R_x

Sodium salicylate	
Sodium bicarbonate	
Sodium baborate aa	30 00
Sig	One-half teaspoonful to a glass of hot water

Persistent coughing exhausts the patient and should be controlled. This may be accomplished by regulating the temperature of the room, by the continuous use of a steam kettle, or the treatment of a sinusitis. If these methods fail, codeine or morphine should be given in effective doses.

I use this prescription

R_x

Codeine	0 008
Ammonium chloride	0 06
Terpin hydrate	0 25
Sig	One capsule q 2 to 4 hours

Another soothing prescription is this

R_x

Spirit of camphor	
Oil of turpentine	
Olive oil aa	60 cc
Sig	Apply to chest on a flannel bib and inhale the fumes

The lips should be protected from cracking by the frequent application of liquid petrolatum. When fever blisters once appear they should be painted immediately with tincture of benzoin. This forms a water-proof coating over the blister and prevents the patient's licking the blister and irritating it. The worst thing you can do for fever blisters is to apply any kind of grease.

Nausea and vomiting present two of the most serious problems in the seriously ill patient. The longer nausea persists and the more a patient vomits the harder it is to control them. The simplest method of con-

trolling nausea is to try to empty the stomach into the intestine rather than to allow the patient to begin vomiting. As long as peristalsis is in force a patient does not vomit. I give a patient repeated cups of hot water until one is held down. Usually by the second or third it is retained. If the hot water is not retained and there is objection to drinking hot water, you can add a little tea or a few drops of essence of peppermint, ammonia, bicarbonate of soda, or salt. People have the idea that hot water will cause vomiting. Hot water will not make a person vomit if really hot, lukewarm water will. At the same time you can apply a mustard plaster to the epigastrium. I usually prescribe mustard plasters small in dimensions so that I may repeat them and not irritate the skin. I use a mustard plaster about 2½ to 3 inches square and place it at different spots over a period of an hour or several hours, as is necessary. If this does not control the vomiting, I give intravenously 50 cc of a 50 per cent solution of glucose. This will stop the vomiting of almost all types. It can be repeated as often as it is necessary.

The carbonated drinks are also helpful. Ginger ale, any of the carbonated waters, Vichy, champagne are all efficacious in relieving mild nausea. Sometimes giving a patient a solid meal will be effective. The use of compound tincture of gentian, 30 minims every fifteen minutes for four doses, followed by a steak which has been cooked rare and well salted, will often stop persistent vomiting. When all of these methods fail, the thing to do is to insert a stomach tube through the nose. If the nose and throat are well cocainized, the stomach tube can be introduced without difficulty. By the use of a stomach tube we can not only wash out the stomach effectively but we can also give fluid and food, which I will mention later.

The question of the bowels is another important one. I never give the patient in bed a cathartic large enough to produce a number of stools. My object always is to give a small enough dose so that the upper bowel will be emptied and then use a small enema to cleanse the lower bowel. Milk of magnesia, in doses of one-half to a tablespoonful or two, acts well. However, if a person has any specific cathartic to which he is wedded, I am always glad to have that used. An enema is by far preferable to cathartics that will require the patient to use the bed pan two or three times. When a patient is extremely ill, I think a high colonic irrigation

is much easier on the patient than an enema because he can lie on his side and the bowels can be washed out without any difficulty.

Diarrhea occurs occasionally in fevers, and usually the first thing I do is to give the patient a dose of castor oil if there is no contraindication to it. That will often stop the diarrhea. If it does not, I follow it up with the use of bismuth in some form—milk of bismuth, bismuth subnitrate, or bismuth subcarbonate. We usually give bismuth in doses too small to be effective. I use a teaspoonful, stir it into water until it is smooth, and repeat this every hour or every two hours for three or four doses.

Distention is another troublesome symptom in fevers. It may be prevented by watching the diet, especially limiting the use of fruit juices and sugar. There was a time when fruit juices, especially orange juice, were given first and to such an extent that patients were blown up, the results being worse than with any other food except, perhaps, the addition of glucose or lactose. So the first thing to do is to cut down the sugars—the carbohydrates in general.

A trick that I learned from one of the nurses is to use a rectal tube, the free end of which is inserted in a urinal that has been prepared as follows. The urinal is filled with boiling water and allowed to stand until hot. It is then emptied, except for a small amount of water to which is added 10 to 15 drops of the essence of peppermint. Then the rectal tube is put into this just above the hot water. The secret of this is the use of hot water which causes a partial vacuum in the urinal and, therefore, aspirates the gas out of the intestine. At the same time that the rectal tube is used, some form of heat, such as a hot-water bag, should be applied to the abdomen. If this does not succeed, wet heat, such as the turpentine stupes, may be used.

If these do not succeed, I often use a milk and molasses enema. I do not know how many of you have ever used this, but it is the most effective form of enema there is. I use 1 cup of molasses and 1 cup of milk, warm each separately, and stir them up together. I suppose it is effective because it is a hypertonic glucose solution. I have never seen it fail. It will always empty the bowel and relieve the patient of distention, at least temporarily.

Then we may use a colonic irrigation preceded by an injection of 10 units of pitressin or pituitrin, about a half an hour before

Pitressin may be repeated half an hour after the first injection, if necessary.

The question of fluid intake must be settled by the output of the patient, by the rate at which the patient is breathing, the amount of sweating, the consistency of the stools, and the volume of the urine. From a practical point of view you can judge the specific gravity of the urine by simply looking at the color. Thirst is also a helpful sign. Patients, I think, should never be allowed to go thirsty, we should not limit their intake to that point. So, you cannot set an arbitrary figure for the amount of fluids you are going to give a patient, but you must be guided by the general picture.

Then there is the question of the method of introducing the fluid. A good nurse can almost always get a sufficient amount of fluid by mouth into even the sickest patient. It is hard to get sufficient fluid through a tube. The best way to introduce fluid into the mouth of a sick patient is by a syringe. Formerly, we used drinking cups and, although they do not seem to be the style any more, they often are helpful.

When a patient is delirious, certainly a glass tube should never be used. There is now on the market a cellophane tube. These are durable and are much better than the old tubes that were made of paper. I use these almost exclusively instead of glass tubes.

If oral feeding fails, I next try feeding by the nasal tube. It has the advantage of enabling you to follow the digestion of the food you are giving and to tell just how rapidly the fluids that are being put into the patient's stomach are being absorbed, because you can aspirate every once in a while to see whether or not absorption is taking place. The use of the stomach tube prevents the discomfort of the use of needles and the fatigue that always follows the use of both clydes and infusions. I try to avoid those as long as I can.

If it is impossible to use a stomach tube for any reason, I like to use an intravenous injection rather than a clysis, because clydes almost always make the legs sore and the patient uncomfortable.

The volume of an injection should never be over 1,000 cc in the ordinary sick patient. In diabetes it is a different matter. Two injections a day are as much as I usually give. The fluid to be used is normal saline solution with or without 5 or 10 per cent glucose. When you are giving a clysis, the skin should always be cocaineized before the introduction

of needles, otherwise the pain from sticking the needles into the leg makes the patient nervous and he is uncomfortable during the entire clysis. If the skin is cocaineized he does not realize he has been stuck and does not appreciate any discomfort unless the leg begins to swell. The amount of fluid to be used in any clysis should not be over 500 cc through each needle, and it should be introduced at a rate slow enough to allow absorption and to prevent the leg from becoming hard.

I prefer not to use sugar solution in clyses. If you have used it often, you know that after one or two injections the absorption is slowed down so that the procedure is painful. The difference between the benefit the patient gets with the small amount of glucose added to the solution and the added discomfort is not worthwhile. A normal saline solution is absorbed quite rapidly. If I feel that a patient needs sugar, I give 50 to 100 cc of a 50 per cent glucose solution intravenously during the clysis. This has the advantage of increasing the rapidity of absorption of the clysis because of the introduction of the hypertonic solution. It is also helpful if hot-water bags are applied over the legs and gentle massage is used frequently during the injection.

The question of sleeplessness, restlessness, and nervousness is extremely important. I think that restlessness and nervousness may be prevented to a large extent by our taking the patient into our confidence in the beginning and letting him know just how sick we feel he is. Another thing that gets the patient nervous and makes him restless is whispering in the patient's room. I think, when we talk in a patient's room it is far better to talk in an ordinary quiet tone of voice than it is to go around whispering. If he is so sick that you have to whisper, he is usually so sick he does not know what you are saying and you only add to his subconscious restlessness.

Cold cloths applied to the head or cold packs and warm baths followed by a gentle massage will do a great deal toward putting a patient into a frame of mind where he will go to sleep. If the patient is nervous and if some form of mild sedative is used during the day, we can prevent the extreme restlessness when darkness comes on. It is a perfectly natural thing that a patient should have a dread of the night, and our object always is to put the patient into a quiet frame of mind before nightfall. One good way to do this is by using small doses of sedative, beginning around

3 or 4 o'clock in the afternoon. I use quite often an old drug that the students probably have never heard of—trional. I usually begin with 0.12 Gm (2 grams) and repeat every two hours for five doses, and by the time the fifth dose is given the patient is usually ready to go to sleep. I also use chloral and bromide a good deal. I usually prescribe it in these proportions: 0.3 Gm chloral and 0.6 Gm bromide, and I give that dose after each meal—at bedtime double the dose. For patients who are unable to go to sleep but who sleep well after its induction, nembutal, phenobarbital, or any other drug of this type is effective. There are a great many people who have a constitutional objection to taking anything to make them go to sleep. These people can be given a sedative by rectum, and they never know they are not getting a plain enema. You can use 0.6 Gm of chloral and 1.2 Gm. of bromide or paraldehyde in doses of 4 to 12 cc in about 100 cc of starch paste. You can also give any of the common sedatives, such as medinal and amytal, in a suppository, using 0.3 to 0.6 Gm.

If one is unable to control sleeplessness and restlessness by these simple methods, a lumbar puncture oftentimes is effective, removing a sufficient amount of the fluid to bring the pressure down to normal.

Formerly, in typhoid fever we always used Brand baths. Nowadays, I do not know whether any men recommend using Brand baths or not, but the cold pack is certainly effective and any nurse knows how to give one.

The question of anorexia is important. When the patient gets over the immediate acute condition, starvation exaggerates anorexia and, therefore, it is wise to feed the patient from the start of the illness. Nothing makes a patient dislike food more than a constant discussion of the food. His chief dislikes should be avoided. His favorite foods had better be shunned too as they rarely meet the patient's expectations. The simplest method is to feed innocuous foods, to feed these in small amounts, attractively served. If they are given every two hours, I think the patient can easily be given the proper amount of calories and still not feel that he is being overfed. The choice of the diet to be given depends to a great extent on the patient's habit of food. As I have said before, often people get tired of liquids and, if you will give them a solid diet, they will take it and take it with pleasure. One of the best things to aid in appetite is to use one of the bitter

wines, vermouth being excellent to relieve anorexia I give 0.5 to 1 ounce of vermouth before meals or with meals, or I use a bitter wine of iron—an old preparation that is often effective

Finally, the vitamin intake must be watched and maintained at an adequate level

DR DuBois Several drugs have been discussed I wonder whether Dr Gold would care to comment on trional

DR HARRY GOLD As Dr Guion has said, it is an old one Sulfonal and trional are sulfone hypnotics that have fallen into disrepute for various reasons They can produce hematuria They are slowly absorbed It takes two hours before sleep is produced, but I notice that the way in which Dr Guion prescribes trional takes account of the slow absorption She starts late in the afternoon, giving small doses, and by evening the patient is ready to fall asleep Trional is not so effective an hypnotic as barbituric acid compounds because, even with fatal doses of trional, it is not possible to produce narcosis It has a restricted capacity to depress the higher centers

DR GUION It is more effective in insanity than the later ones, and it is used in some institutions for the insane in preference to some of the more modern products Sulfonal is absorbed slowly, but the trional is absorbed much more rapidly and acts much more quickly Oftentimes you can give a combination of trional and sulfonal and thus keep the patients asleep all night, whereas if you use sodium amytal, for instance, the patients will stay asleep for two or three hours and then they are just as wide awake as they were in the beginning

DR GOLD This shows high persistence of action, which is in line with the results in the laboratory

DR DuBois Do we use them here?

DR EDWIN J DORY We have not had any experience with trional We sometimes use sulfonal in small doses

DR DuBois Do you have any other comments, Dr Gold, on the various drugs or combinations of them used here? Have you seen any incompatibility?

DR GOLD No, not at all I did have a question in mind about the pitressin In what dosage in cubic centimeters was that given?

DR GUION I use $\frac{1}{2}$ cc for the first dose and repeat in half an hour if it is necessary, so sometimes a total of 1 cc is given, but very often $\frac{1}{2}$ cc is all that is needed

DR GOLD Is that a $\frac{1}{2}$ cc of the material with 20 units or 10 units per cubic centimeter? The reason I ask is because there has been some change in the concentration in which it is being put out now

DR GUION I think it is the 20-unit

DR GOLD Does it not make them sick?

DR GUION No

DR C H WHEELER That is the same as we use here in the hospital on the Medical Service I would say, as a rule, we give 1 cc rather than $\frac{1}{2}$ cc

DR GOLD Ten units per cubic centimeter?

DR WHEELER Of that I am not sure

DR GOLD Some time ago a representative of the manufacturer called my attention to the fact that they are now also putting out a pitressin ampule in 10 units to the cubic centimeter I wondered why He said that the doctors were in the habit of injecting the 1 cc of the 20-unit per cubic centimeter material As a result, the patient often turned pale and cold, developed a hellyache, and sometimes vomited They had persuaded some to give only $\frac{1}{2}$ cc but could not persuade all to give less than 1 cc, so they took the strength out from under and put only 10 units in 1 cc

DR GUION Sometimes they do get pale, but I never have seen one who became nauseated or vomited Sometimes the pulse gets quite slow

DR GOLD Would you have any fear of giving it to elderly people suspected of coronary disease or is that not a contraindication?

DR GUION Elderly patients with coronary disease do not usually become distended, and I have never given it to one If such a person were distended and if I could not control it any other way, I would give it, because I think the distention would be more uncomfortable than the reaction

DR GOLD I have in mind the constriction of the coronary arteries by pitressin

DR McKEEN CATTELL I was interested in the choice of the type of hypnotic you use Apparently, what you are after is not the use of substances that are primarily narcotic in their action I suppose the bromides and trional fall into a class tending to bring about relaxation and mental calm, with a decrease of activity but less true narcotic action

DR GUION I think that is what you desire You want to have them calm because then natural sleep will follow

DR DuBois Do you double the dose of chloral when given by rectum?

DR. CATTELL I would be surprised if that were necessary

DR. GUION I double the last dose to carry them through the night and not because it is given by rectum

DR. GOLD How does tincture of nuxvomica stop the vomiting or nausea?

DR. GUION Because it is bitter I think you could use tincture of gentian or, perhaps, any other bitter agent

DR. CATTELL The dose is probably too small to have any systemic effect?

DR. GUION I think that is so

DR. DuBOIS If you use 10 minims of the tincture to the dose, you would have to use 25 drops because the drops of a tincture are small

DR. EDWARD TOLSTOI I should like to make one or two additions to Dr. Guion's remarks It is my policy, in addition to explaining everything rather frankly to the patient, as much as circumstances will permit, to take the members of the family aside and acquaint them with the situation, because it is important to have their cooperation This will save a lot of trouble and avoid the necessity of issuing hourly bulletins over the telephone to the aunt and second cousin or others I recall Dr. Connor's wise words to a patient he was good enough to help me with This was a typhoid fever patient who was in his third week He was suffering from a bad headache and was extremely restless Nothing helped, not even morphine. I asked Dr. Connor to see the patient, and he sat down at the patient's side The patient said to him "I feel terrible, terribly sick. This is the sickest I have ever been"

Dr. Connor said to him "I do not doubt that, but I think you are going to be a little sicker before you are well" The patient appreciated this frankness

I wonder what role the vitamins play in a fever of six to seven weeks' duration The patient eats little or nothing at all We are likely to be more concerned with fluids than with food. The patient may become irrational after a while and refuse everything by mouth. Under such conditions we now give some vitamin B₁, 300 or 600 units twice a day Today, that is the fashion, but I do not know how helpful it is I would like to hear that point discussed

DR. DuBOIS I wonder if the matter of rest is not so important as to deserve a special prescription written in the book that the patient is not to be touched or spoken to between such-and-such hours I certainly

wish it were that way We have an hour in the wards I wish we could have more than one hour during the day

DR. GUION With regard to what Dr. Tolstoi has said about the vitamins, I think the advantage of feeding these patients by a nasal tube is that you can give a balanced diet and you can give all the vitamins I frequently put a nasal tube down the nose of my pneumonia patients and begin soon to feed them all the calories I think they need and give them the proper proportion of the three food elements I always add to this the juice of vegetables, so that I get the minerals out of the vegetable juices and then pour down vitamins I do not know whether they need them or not but I know it does not do them any harm. You can keep a nasal tube down for a week or two weeks without any trouble If you pour some oil down the nose two or three times a day, the patients will not mind the tube They do not even know it is there It is a simple way to feed a sick patient who has no appetite

DR. TOLSTOI How important is food in the short illness of, say, two weeks? I know in typhoid fever the attempt is made to keep up the caloric balance All of us who have had fever know our appetite is gone, and we are grateful if we are just left alone.

DR. DuBOIS I doubt if it is important enough to plague the patient to death but there certainly should be moderate amounts of food I do not know how we could determine it except by controlled experiments on a large series of patients With the present fad of giving vitamins to everyone we should be able to see a change in the picture of the infectious diseases if the vitamins are really important I should not be surprised if it is found much easier to take care of the mouth when the proper parts of the vitamin B complex are given. I do not know It is an impression based on the experience in typhoid fever where the mouth condition cleared up with surprising rapidity when the patients were given a certain amount of food I do not think it was due to the calories but rather to the vitamins.

DR. WHEELER I have the impression, Dr. Guion, that you do not make as much effort to force fluids in patients with febrile diseases as we do in the hospital It seems to me in those cases one of our chief aims, rightly or wrongly, has been to get them to take in the ordinary amount of water

I looked over the charts of 10 of our patients with typhoid fever, all of whom ran

wines, vermouth being excellent to relieve anorexia I give 0.5 to 1 ounce of vermouth before meals or with meals, or I use a bitter wine of iron—an old preparation that is often effective

Finally, the vitamin intake must be watched and maintained at an adequate level

DR DuBois Several drugs have been discussed I wonder whether Dr Gold would care to comment on trional

DR HARRY GOLD As Dr Guion has said, it is an old one Sulfonal and trional are sulfone hypnotics that have fallen into disrepute for various reasons They can produce hematorporphyrinemia They are slowly absorbed It takes two hours before sleep is produced, but I notice that the way in which Dr Guion prescribes trional takes account of the slow absorption She starts late in the afternoon, giving small doses, and by evening the patient is ready to fall asleep Trional is not so effective an hypnotic as barbituric acid compounds because, even with fatal doses of trional, it is not possible to produce narcosis It has a restricted capacity to depress the higher centers

DR GUION It is more effective in insanity than the later ones, and it is used in some institutions for the insane in preference to some of the more modern products Sulfonal is absorbed slowly, but the trional is absorbed much more rapidly and acts much more quickly Oftentimes you can give a combination of trional and sulfonal and thus keep the patients asleep all night, whereas if you use sodium amytal, for instance, the patients will stay asleep for two or three hours and then they are just as wide awake as they were in the beginning

DR GOLD This shows high persistence of action, which is in line with the results in the laboratory

DR DuBois Do we use them here?

DR EDWIN J DORR We have not had any experience with trional We sometimes use sulfonal in small doses

DR DuBois Do you have any other comments, Dr Gold, on the various drugs or combinations of them used here? Have you seen any incompatibility?

DR GOLD No, not at all I did have a question in mind about the pitressin In what dosage in cubic centimeters was that given?

DR GUION I think that is what you desire You want to have them calm because then natural sleep will follow

DR DuBois Do you double the dose of chloral when given by rectum?

Thirty-Fifth Annual Meetings of the District Branches of the Medical Society of the State of New York

PROGRAMS

es

First District Branch

Wednesday, October 8, 1941
Mount Sinai Hospital, 100th Street & Fifth Avenue
New York City

General Information

Place of Meeting—Mount Sinai Hospital
Physicians are requested to enter through the
sempriate pavilion on 1 East 100th Street,
where registrars will distribute latest information
regarding special clinics

Luncheon The hospital, through its director,
Dr Joseph Turner, has invited the members at-
tending the session to be its guests at luncheon,
which will be served at 1 00 P M in the nurses'
dining room

Business Meeting Will be conducted in the
dining room during lunch hour—1 00 P M to
2 00 P M

Program Dr Reuben Ottenberg, chairman
of the Hospital Committee on Medical Instruc-
tion, has enlisted the cooperation of the entire
hospital staff to provide an all-day program
covering the entire field of medicine except
obstetrics

Map The engineering staff of the hospital
has prepared a floor plan. Reference to this
map will aid in locating the exhibits. In the
listing the letters are used to designate the build-
ing the numbers, the floor

Appreciation To the members of the hospital
staff who have cooperated in the presentation of
the program

To Mr MacDonald of the engineering staff of
the hospital for his cooperation in the prepara-
tion of floor plans, signs, and guide markings

To Miss Edith Levy, secretary for the Com-
mittee on Medical Instruction, for her kind
assistance in gathering and arranging material

General Medicine

Ward Rounds

2 00- 3 00 Dr Bachr and staff F-5
2 00- 3 00 Dr Moschowitz and staff I-3

Round Table

11 00- 1 00 Endocrinology G-2
Drs Silver and Soffer

Case Presentations

D-3

9 00- 9 20 Insulin Resistance Dr C Spingarn
9 20- 9 40 Vitamin Deficiencies Dr M Ellenberg
9 40-10 00 Diabetic Coma Dr H Dolger
10 00-10 20 Bright's Disease Dr A. Fishberg
10 20-10 40 Jaundice Dr R Ottenberg
10 40-11 00 Diabetes Mellitus Dr H Pollack
11 00-11 20 Circulatory Dynamics Drs Hitzig—King
11 20-11 40 Cardiac Efficiency Dr H Jaffe
11 40-12 00 Cardiac Emergencies Dr A. Master

3 40- 3 50 Transfusion Reactions Dr P Vogel
3 50- 4 00 Epistaxis Dr S Peck

a temperature between 40 and 41 C for a week or longer, and during that period the average fluid intake was about 3,500 cc a day, with an extreme of 8,000 cc a day down to 1 who took only 1,000 cc a day. I wonder what your experience has been about the volume that is ordinarily required.

DR GUION I think it is just as important not to drown a patient as it is not to curtail his fluids. Patients are quite frequently drowned in their own intake. Certainly, Dr Helper's experience on that point in autopsy work at Bellevue has shown that patients who have had large volumes of fluid have fluid in the abdomen and chest, and their tissues are definitely oversaturated.

I give my patients between 2,500 and 3,500 cc, and, except in diabetes, I rarely give patients more than 3,500 cc. It depends, as I said, on how much fluid they are losing. If a patient is breathing rapidly and I feel they are losing a lot of fluid in their breath and if they are sweating profusely, then I run up the amount to 4,000 or 4,500, but I never give anybody more than 4,500 cc of fluid. I do not think it is necessary. You look at the urine of the person getting 3,500 cc, and it is straw colored or water white and has a low specific gravity. This patient is satisfactorily hydrated. I do not see what you gain by running the fluid up so high above a normal intake.

DR DUBOIS If I remember rightly, about five years ago there appeared an article in the *Journal of the American Medical Association* entitled, "Water, Water Everywhere." It is a magnificent discussion of the fad about oversaturating our patients with water.

Summary

DR GOLD The following factors in the treatment of the seriously sick patient have

been elaborated in the discussion: the pathologic appraisal of the patient, his enlightenment concerning the nature and course of his disease, the choice of the nurse, the sick room, the behavior of the attendants, the bath, the care of the skin, the bed and the sheets, the care of the mouth and teeth, the throat, and lips, the control of cough, the fever blister, the control of nausea and vomiting, the type of diet, the variety of routes for feeding, the control of constipation, diarrhea, and distention, the fluid intake, the vitamins, the control of restlessness and insomnia. Few are the drugs required for the effective management of the seriously ill patient. A cathartic, a sedative, a mouth wash, a gargle, and a cough remedy practically complete the list.

As a result of the rapid progress in recent years in the discovery of specific cures for specific diseases, the doctor's interest in the disease has tended to eclipse his interest in the patient. The general management of the seriously sick patient stands in danger of neglect. Perhaps it is natural, for with the use of sulfonamides, by way of illustration, the course of a disease such as pneumonia has been so profoundly affected—its severity reduced, its duration curtailed—that often before one gets around to thinking of the patient his disease is over. There are many diseases, however, in which that is not yet the case, and it is refreshing to contemplate the detailed account of the many measures presented here which can be applied to the sick person, even in the absence of specific cures, which ease the burden of a serious and prolonged illness and preserve the natural body forces to combat the disease and insure recovery. It is a noteworthy aspect of this conference on treatment that in the center of interest stands not the disease but the patient.

MADE A DIFFERENCE

"Doctor," said the patient, "If there's anything the matter with me, don't frighten me to death by giving it a long scientific name, but just tell me what it is in plain English."

The doctor examined the man thoroughly and then said, "Well, to be quite frank, there's nothing the matter with you. I should say you were just lazy!"

The patient looked rather discomfited and said, "Now give me the scientific name for it—the longest name you've got. I've got to report to my employer."

—*Buffalo Courier Express*

SOME MORE SULFUROUS, TOO

A New York physician was giving an informal talk on physiology upon the windy, sea-fronting porch of an Atlantic City hotel.

"Also," he said, "It has lately been found that the human body contains sulfur."

"Sulfur!" exclaimed a girl in a blue and white blazer. "How much sulfur is there, then, in a girl's body?"

"Oh," said the physician smiling, "the amount varies."

"And is that," ask the girl, "why some of us make so much better matches than others?"

District Branches will appear in a later issue}*

Fifth District Branch

Tuesday, September 23, 1941
Hotel Syracuse, Syracuse, New York

Morning Session (9 30 Daylight Saving Time)

"The Use of Steel Wire Sutures in General Sur-
gery" (Motion Picture)

H Dan Vickers, M D, Little Falls,
N Y
Joseph W Conrad, M D, Little Falls,
N Y

Walter M Boothby, M D, Rochester, Minn., *professor of experimental metabolism, the Mayo Foundation, and Director of the Laboratory for Research in Aviation Medicine*

Norman H Jolliffe, M D, New York City, *associate professor of medicine, New York University College of Medicine*

"Clinical Applications of Recent Advances in Nutrition"

Ladies will be entertained at luncheon at the Cooperstown Country Club

Seventh District Branch

Thursday, September 25, 1941
Oak Hill Country Club
Rochester, N Y

The Oak Hill Country Club is located on Route N Y 2, between Pittsford and Rochester and is easily reached from all points of the District. In approaching Rochester from the east and south, drive on north through Pittsford. The club entrance is on the west side of the road and has its name in large letters at the gate. It is within one-half mile of the left turn toward Rochester, known as the East Avenue Road. The clubhouse is some distance back from the entrance gate and ample parking space is provided.

Morning Session (Daylight Saving Time)

1 15 P M Luncheon and Introduction of Guests

9 30 Registration at Oak Hill Country Club

10 00 Motion sound pictures, under the direction of Benjamin J Slater, M D, Rochester, N Y

"More Trifles of Importance"

"XXX Medico"

"The Hidden Master"

"A Way in the Wilderness"

Metro-Goldwyn-Mayer pictures recently released. These pictures have been selected for their inspirational and historical value in regard to advances in medicine and surgery.

11 00 "Plasma Proteins and Clinical Problems"
George Hoyt Whipple, M D, *dean and professor of pathology, University of Rochester School of Medicine, Rochester, N Y*, with associates—Drs S C Madden, E B Mahoney, and J W Howland

A great deal of work is being done in the Rochester School of Medicine relating to plasma proteins, and this group is particularly able to give information on this subject which is, at the present time, of tremendous interest in civil and military surgery.

12 00 "The Diagnosis and Treatment of Lesions of the Cranial Nerves"
Walter E. Dandy, M D, *adj professor of neurosurgery, Johns Hopkins University School of Medicine, Baltimore, Maryland*

This address contains the results of much research and experience during the past decade and is concerned with trigeminal neuralgia, glossopharyngeal neuralgia, Ménière's disease, carcinoma of the tongue and spastic torticollis, also tumors and aneurysms affecting the cranial nerves.

Discussion William P Van Wagenen, M D
Henry Ward Williams, M D
Rochester, N Y

2 00 Business Meeting—Election of Officers

Afternoon Session—Forum on Medicine and Surgery

The afternoon session will be devoted to a forum which will be composed of four panel discussions as follows, beginning at 2 15 P M. Members may select the group which they prefer to attend, designated by colored cards obtainable at the registration desk.

1 "Health and Disease in Infancy and Childhood"

The subjects discussed will be those which have a practical value and are problems in which many members of the Society are interested.

"Treatment of Convulsive Disorders in Infants and Children"

"Diagnosis and Treatment of Whooping Cough"

"Vitamin and Mineral Needs of Infants"

"Rational Procedures in Eczema and Allergic Disorders"

"Tuberculosis Control in Children"

"Diagnosis and Management of Rheumatic Infection"

Conductor Albert D Kaiser, M D

Assistants John Aikman, M D, Paul W Beaven, M D, William L Bradford, M D, Samuel W Clausen, M D, and Jerome Glaser, M D

2 "Modern Drug Therapy"

Under this heading, not only the therapy of the sulfonamide group is brought up to date, but a discussion of vitamin therapy will be taken up.

Conductor James H Sterner, M D

Assistants Stanley H Elenback, M D, Thomas Killip, M D, John S Lawrence, M D, C Stewart Nash, M D, Henry C Shaw, M D, Leo F Simpson, M D, and Karl M Wilson, M D

This picture covers work done by these physicians in the Little Falls Hospital over a period of three years

"Blood Stream Infection of the Cortex of the Kidney"

Leo E. Gibson, M D, Syracuse, *associate professor of urology, Syracuse University College of Medicine*

Description of the mode of infection and the pathology involved. Discussion of the different types with the signs and symptoms referable to each. The importance of a careful history as the most important aid in the diagnosis is stressed. Cases exhibiting the interesting vagaries of the disease will be presented with the aid of lantern slides.

"Facilities, Personnel and Waters as Presented for Treatment at the Saratoga Spa"

Walter S. McClellan, M D, Saratoga Springs, N Y, *medical director, Saratoga Spa*

"New Concepts of the Etiology of Cancer"

William H. Wehr, M D, Buffalo, *surgeon, State Institute for the Study of Malignant Disease*

Discussion of various types of cancer with the accepted forms of therapy and the end results of treatment.

Luncheon and Introduction of Guests

Afternoon Session (2 00 P M)

Business Meeting—Election of Officers

"Chronic Arthritis from the Standpoint of the Practicing Physician"

Howard K. Thompson, M D, Boston, *asst professor of medicine, Tufts Medical School, head of Arthritis Clinic, Boston City Hospital, Robert Breck Brigham Hospital*

What is meant by orthodox or conventional treatment?

What is the latest theory as to the cause?

What about vaccine? And the rumour about gold salts, diet, and proteins?

Is there any campaign a family physician can carry out without elaborate equipment and hospitalization?

"Blood Studies in Shock as a Guide to Therapy" (Illustrated by slides and motion pictures)

John Scudder, M D, New York City, *instructor in surgery, College of Physicians and Surgeons, Columbia University*

There are certain tests, which can be readily mastered, of more value than blood pressure determination in the anticipation of shock. These tests measure loss of fluid from the blood. In following a case of shock, the sensitivity of these tests can differentiate between shock due to trauma or dehydration and shock due to hemorrhage. Thus, internal hemorrhage can be detected before fall in blood pressure or before clinical manifestations of blood loss.

"The Modern Care of Civilian and Military Casualties Under Warfare"

Charles Bove, M D, New York City, *surgeon in charge of a general hospital in Paris at the time of the invasion of Paris*

A description of the medical setup under present warfare conditions.

Entertainment for Ladies

The ladies will join with the members of the District Branch for luncheon and in the afternoon will be entertained by the Onondaga County Auxiliary.

Sixth District Branch

Thursday, September 18, 1941
The Mary Imogene Bassett Hospital
Cooperstown, New York

Morning Session (10 00 A M Daylight Saving Time)

"The Medical Examiner and the Coroner—Is New Legislation Needed?"

Gilbert Dalldorf, M D, Valhalla, *director, Division of Laboratories, Grasslands Hospital*

"Diagnosis and Rationale in Treatment of Carcinoma of the Breast"

Hugh Auchincloss, M D, New York City, *professor of clinical surgery, College of Physicians and Surgeons, Columbia University*

"Involutional Melancholia"

Edward A. Strecker, M D, Philadel-

phia, *professor of psychiatry, University of Pennsylvania School of Medicine*

Luncheon and Introduction of Guests

Afternoon Session (2 15 P M)

Business Meeting—Election of Officers

"Management of the Patient with Cardiac Pain"

Robert L. Levy, M D, New York City, *professor of clinical medicine, College of Physicians and Surgeons, Columbia University*

"The Physiology of High Altitude Flying" (Motion Pictures)

BETSY ROSS HOUSE on Arch Street in Philadelphia. It was in this house the first flag of the United States was conceived and sewn in 1777. The building is still standing.

Bēpron

REG. U. S. PAT. OFF.

BĒPRON is indicated in the treatment of the nutritional anemias. BĒPRON is a palatable, complete preparation which contains all the desirable soluble constituents of fresh whole beef liver as well as added soluble ferrous iron.

Supplied in 8-oz. and pint bottles

WYETH'S BEEF LIVER WITH IRON

3. "The Gastrointestinal Tract from Medical and Surgical Points of View"
- Some of the topics that will be covered are
- "Diagnosis of Gastritis Made with a Gastro-scope"
 - "The Comparative Merit of X-Ray and Gastroscopy in the Diagnosis of Diseases of the Stomach"
 - "Mechanical Laxatives"
 - "Congenital Lesions"
 - "Psychic Basis and Treatment of Certain Gastrointestinal Symptoms"
 - "X-Ray Investigation of the Duodenum"
- Conductor W J Merle Scott, M D
- Assistants Lyman C Boynton, M D, Sol C Davidson, M D, Thomas B Jones, M D, Labby Pulsifer, M D, George H

- Ramsey, M D, Harry L. Segal, M.D, and Ellis B. Soble, M D
4. "The Puerperal Period and Its Complications"
- This discussion will cover the following
- "The Use of Sulfanilamide"
 - "Blood Transfusion"
 - "Puerperal Morbidity Due to Extra-Pelvic Conditions"
 - "Puerperal Hemorrhages Early and Late"
 - "Conditions Found at the Postnatal Examination at Six Weeks"
- Conductor James K. Quigley, M.D
- Assistants Ward L. Ekas, M D, Shirley R. Snow, Jr, M D, Joseph B. Loder, M.D, James W. Thomson, M D, and M. Edgerton Deuel, M D

RETURN YOUR INFORMATION CARD FOR THE A.M.A. DIRECTORY PROMPTLY

About September 1, an information card will be sent from the headquarters office of the American Medical Association to every physician in the United States and Canada. The information secured is to be used in compiling the Seventeenth Edition of the *American Medical Directory*.

The directory is prepared at regular intervals in the Biographical Department of the American Medical Association. The last previous edition appeared in 1940. This volume is one of the most important contributions of the American Medical Association to the work of the medical profession in the United States, it has been especially valuable in the medical preparedness program. In it, as in no other published directory, are dependable data concerning physicians, hospitals, medical organizations, and activities. The directory provides full information concerning medical colleges, specialization in the field of

medical practice, memberships in special medical societies, tabulations of medical journals and medical libraries and, indeed, practically every important fact concerning the medical profession in which any one might possibly be interested.

Before filling out the information card, read the instructions carefully. Physicians are especially urged to state whether or not they are on extended active duty for the Medical Reserve Corps of the United States Army and Navy.

Fill out the card and return it promptly whether or not a change has occurred in any points on which information is requested. If a change of address occurs before March 1, 1942, report it at once. Should you fail to receive a card before the first of October, write at once to the headquarters office stating that fact and a duplicate card will be mailed.

WHEEL CHAIR ERAS

With the Census Bureau reporting that Americans may
look forward to a longer stay on earth, it is apparent that
the problems of old age are to be multiplied, especially
where infirmities are evident.

Old age pensions and other forms of legislation for
later-life security have their limitations and cannot pro-
vide the actual care required or the absolute rest and
peacefulness that veterans of life have earned. In dis-
cussing the subject of longevity, the *American Profes-
sional Pharmacist* of July states that the number of per-
sons over 65 has increased three million within the last
ten years and predicts the approaching need of "more
wheel chairs and less baby powder."

The A. P. P. recognizes that the medical profession has
partially solved the challenge of an increased span of
life, but in doing so our medical scientists have created
new problems such as finding markets for certain mer-
chandise, old age pensions and security, and a change in
the balance in national customs and social laws.

But the job of the medical profession primarily is to
save lives and to preserve life, although in rehabilitating
patients it often solves their economic problems as well,
and in many respects the medical profession has already
provided for the care of the aged. If we must think of a
'ripe old age' as a wheel chair era then we must con-

sider old age as much a medical problem as a social one.

True, many old folks are invalids actually or figura-
tively and require special facilities for their welfare
and special nursing care. The wants of those on in
years are generally few and simple. For the most part,
they want quiet, some physical comforts and some one to
pay them a little attention and a little of the respect
their senility rates.

Not all are fortunate in having really devoted relatives
who never begrudge the burdens of constantly attending
an aged member of the family. Some, even with such
devoted offsprings, cannot be adequately cared for in the
average American home.

So we have the sanitarium and the nursing home spe-
cializing in the care of elderly people, attractive places
with pleasant environments and so well equipped for
the comfort of the aged and able to provide the special
diets and nursing so necessary in making their declining
years easier and less pain-ridden.

If the sanitariums and nursing homes performed no
other service, the one humanitarian role of devotion to
the care of those who have reached the "arm chair era"
would alone be sufficient to make their place in health
work worthy of full recognition.

Civilian Defense

From the Office of Civilian Defense in Washington, D C, comes information of certain new appointments

A Medical Advisory Board has been appointed by the United States Director of Civilian Defense to assist the Medical Division of the Office of Civilian Defense The following is the personnel

Dr George Baehr, New York City, *Chairman*
Dr Robin C Buerki, Madison, Wisconsin
Dr Elliott Cutler, Boston
Dr Oliver Kiel, Wichita Falls, Texas
Dr Albert McCown, Washington, D C
Dr Fred Rankin, Lexington, Kentucky

Dr H Van Zile Hyde, senior surgeon, United States Public Health Service, has been assigned as Medical Officer in the Office of Civilian Defense for the Second Defense Area located at 111 Eighth Avenue, New York City Dr Hyde will be available for advice and consultation in the development of plans for the establishment of "Emergency Medical Services," as provided in *Bulletin No 1*, Medical Division, United States Office of Civilian Defense, which is about to be issued and distributed.

Volunteer Nurses' Aides

The United States Director of Civilian Defense, Mayor F H LaGuardia, announces the training of 100,000 Volunteer Nurses' Aides during the next twelve months, in collaboration with the American National Red Cross and the major hospitals of the country The program is in preparation for a great expansion in hospital beds which may be required during the National Emergency, at a time when the already overburdened nursing facilities of civilian hospitals are seriously depleted due to the demands of our military and naval establishments and the increasing needs of public health and industrial hygiene services

The growing deficiency in hospital personnel is now being met in part through the training of large numbers of paid subsidiary hospital workers by the NYA, WPA, and other agencies The training program for Volunteer Nurses' Aides is designed to expand the effectiveness of the trained nurse in hospitals, clinics, and field nursing services by supplying her with intelligent assistants who can work under her direction

The curriculum of instruction has been prepared by the Medical Division of the Office of Civilian Defense, the American National Red Cross, and the Federal Security Agency Eligibility is limited to women between the ages of 18 and 50 who have had at least a high-school educa-

tion or its equivalent and who are physically fit The course will provide eighty hours of intensive instruction in a period of seven weeks The first half of the course will be given in the local Red Cross chapter house in collaboration with local hospitals and nursing organizations This will constitute the probationary period and will require two hours of instruction daily on five days a week for four weeks

The second half of the course will consist of supervised practice in a hospital which has been designated by the Office of Civilian Defense and the Red Cross as a Training Center The American National Red Cross will assist the hospital to provide competent instructors and nursing supervisors

Those who complete the course will be enrolled in the Volunteer Nurses' Aide Corps of the American Red Cross with the assurance that they will play an important role in Civilian Defense They will retain their membership in the Corps only as long as they continue to render adequate service during the period of the National Emergency This is defined as 150 hours of volunteer service in a hospital, clinic, or field nursing organization in at least one three-month period in each calendar year

The Office of Civilian Defense and the American National Red Cross will provide for this continuing service by arrangement with local hospitals and field nursing agencies For this purpose the Red Cross will maintain a Placement Bureau, which will allocate Volunteer Nurses' Aides to the following types of nursing service hospitals and clinics, visiting nurse (home visiting) agencies, health departments, school health services, and industrial hygiene clinics

By serving in this manner as assistants to qualified nurses, their training will be continued In the event of sudden emergencies during a period of national crisis, they will then be immediately available for reassignment to hospital or field duty by the Office of Civilian Defense There will be opportunity for some to serve as members of the Mobile Medical Field Units which are being organized in hospitals along both seaboards and in industrial centers in the interior, according to plans announced this week by the United States Office of Civilian Defense

Volunteer Nurses' Aides will wear the uniforms and insignia of Civilian Defense The new insignia for Nurses' Aides will be a red cross within the triangle and circle of the OCD, indicating that the Aide was enrolled and trained by the Red Cross to service in Civilian Defense

Applicants may enroll at the Red Cross chapter house and the course will begin in each locality as hospital arrangements are completed

THE LATEST WRINKLE

Patient "What does the price include, doctor?"

Doctor "The price includes the operation,

ten days in the hospital, and a medical dictionary so you can hold your own at bridge games"

"TRAVEL MEDICINE"

CANADA, always a colorful vacation retreat—summer or winter—is even more so now in its warlike, though peaceful, setting.

In nearly every Province the country to our north offers a pageant of war personalities. Ottawa is a city of picturesque contrast, presenting the aspects of a boom town through its new war buildings and war population. A step from the United States Embassy are street scenes of multicolored uniforms where soldiers of Poland, Belgium, Holland and Norway mingle with comrades wearing the dark blue of the Royal Canadian Navy, the light blue of Aviation and the khaki and blue from all points of the British Empire.

Coupled with the diplomatic and military life of the capital are the Royal exiles and families of Netherlands and the grand duchy of Luxembourg. Canada with its 66 training schools is the hub of the Empire's air forces and vacationists soon become acquainted with the uniforms from far away lands seen everywhere. The Dominion air schools now draw recruits from New Zealand, Australia and the most remote of British possessions. In addition to American volunteers in training are students from Mexico, Peru and Argentine. Outside Toronto is "Little Norway" where the Royal Norwegian flyers are forming a unit for Canada's fighting.

Eighty-seven members and friends of the Academy gathered at the Orchard Park Golf Club on July 10 for the Annual Field Day of the Buffalo Academy of Medicine. Golf, bridge, and much conversation preceded the annual "victory" dinner, at which all manner of awards and prizes made their appearance.

The new officers of the Buffalo Otolaryngological Society for the next year are: president, Dr Morris E Newman, vice-president, Dr Leon H Smith, secretary, Dr Joseph G Krystaf, and treasurer, Dr Joseph C Scario.

As a part of the National Defense Program, Buffalo has been called upon to establish a collection center and volunteer donor bureau to collect blood for transfusion purposes. Buffalo is the fourth city in the United States in which the American Red Cross has established such a center under the supervision of the National Research Council, says the *Bulletin* of the county society.

Dr Paul W Searles of the Buffalo General Hospital has been appointed chairman of the local Blood Procurement Service, and the collection center has been established at the General Hospital through the courtesy of Dr Fraser D Mooney, superintendent. Dr David K Miller of the Edward J Meyer Memorial Hospital has been selected by the National Research Council as their representative to supervise the local project. Dr E Hoyt DeKleine has been named by Dr Searles as vice-chairman of the Blood Procurement Service.

Collections of blood are made daily, and after refrigeration the whole blood is shipped immediately to laboratories in Philadelphia, where the plasma is processed for storage in the dry state.

The quota for Erie County calls for fifty donors per day and the task of enrolling such large numbers is a tremendous project, requiring the assistance of all who can devote their time to the work. There is only a limited budget for campaign purposes.

One of the chief hurdles to overcome is the public's fear of transfusions which arises from the heroic values assigned to transfusions in the not too distant past.

The medical profession can be of invaluable assistance by volunteering themselves as donors early in the campaign. In addition, they should disseminate the real facts about transfusions, the care with which this work is now performed, the physical checks made beforehand, and the function of the National Research Council in its advisory and supervising capacity.

By carefully and sincerely presenting this project to the public, we can be of great help in furthering this program and thereby serve our country in a national cause.

Physicians should contact the American Red Cross or the office of the Medical Society of the County of Erie and obtain a supply of donor

enrollment blanks and other information, in order that they may be informed when asked about the Blood Procurement Service. The Buffalo Blood Procurement Service (American Red Cross) telephone number is CI 1182.

The Medical Society of the County of Erie strongly urges its members to cooperate to the fullest extent in this undertaking, and it is hoped they will inform their patients of its importance in the National Defense Program.

Jefferson County

Dr Harold L Gokey, Alexandria Bay, former president of the county medical society, was elected chairman of the County Health Preparedness Committee at the organization meeting held in the supervisors' room of the county building on August 6.

Kings County

The Friday afternoon lectures, held at 4 30-5 30 P M in the MacNaughton Auditorium, are announced as follows for October and November.

October 3—"The Present Concept of Colitis and Its Management"—Dr Burnell B Crohn, New York City.

October 10—"Hernia"—Dr Alfred H Iason, Brooklyn.

October 17—"The Approach to Differential Diagnosis of Medical Conditions"—Dr George A Sheehan, Brooklyn.

October 24—"Recent Concepts of Rickettsial Diseases: Endemic Typhus (Brill's Disease), Its Diagnosis and Frequency"—Dr Simon R Blatteis, Brooklyn.

October 31—"Recent Advances in Digitalis Therapy with Particular Attention to the Use of Pure Glycosides"—Dr Arthur C DeGraff, New York City.

November 7—"Migraine and Epilepsy"—Dr Leo M Davidoff, Brooklyn.

November 14—"Evaluation of Drug Therapy in Heart Disease"—Dr Harry Gold, New York City.

November 21—No Lecture—(Thanksgiving Holiday).

November 28—"A Consideration of Essential Hypertension as a Metabolic Disease"—Dr Homer Smith, New York City.

The Round-Table Conferences on Mondays at 4 30 P.M. in the MacNaughton Auditorium are announced as follows for October 6 to December 1.

October 6—"Problems in the Management of the Diabetic Patient"—Dr George E Anderson and Dr Edmund L Shlevin, Brooklyn.

October 13—No Lecture—Holiday (Columbus Day).

October 20—"The Medical and Surgical Management of the Tuberculous Patient"—Dr Charles E Hamilton and Dr Edwin J Grace, Brooklyn.

New York County

While other factors contribute to stillbirths and infant deaths within the first ten days of life, prematurity remains the most important single cause of mortality in this group, notes the *New York Medical Week*, and it adds that the Special Committee on Infant Mortality of the Medical Society of the County of New York has therefore emphasized the study of prematurity in the past year. It has investigated all phases of the subject, including pathology, the pediatric care of the premature, obstetric factors tending to prevent premature births, and various public health considerations. It will continue to devote special attention to this question until prematurity has been eliminated as an important cause of infant deaths.

Altogether, however, infant mortality is one of the bright spots in the annals of medical practice and public health. In the past twenty years it has declined 45 per cent throughout the nation. Moreover, the drop has been a progressive one and shows no sign of slackening. If the present local rate for 1941 continues, this year will close with the lowest rate in the history of New York City.

Naturally, the county society does not attribute this progress solely or even chiefly to the activities of its Special Committee. In its efforts the latter has had the assistance of the Department of Health, the Maternity Center, and many individual physicians. There is no doubt, however, that this collaboration has proved mutually beneficial, and the Committee's work "may properly be considered" as having contributed to the noteworthy gains that have

been achieved and are in the process of making.

Dr Kirby Dwight's yacht "Flyaway" came in second in the Eastern Long Island handicap class race, staged as the choice event in the Eastern Long Island Racing Regatta which was held during this season.

Queens County

The Graduate Education Committee propose to initiate courses in Fractures and General Medicine for this fall or winter. Will members of the society who are interested in these courses please signify their interest by communicating with the Chairman of the Committee through the society's office.

A tentative program has been drawn up for a course in allergy to be given for the society in October. Arrangements are being completed through the chairman of the State Society's Committee on Public Health and Education. It is requested that those interested communicate with the chairman of our Graduate Education Committee. Attendance will be gratis.

St Lawrence County

The county society met in Ogdensburg on August 7 and, after a luncheon at the country club, enjoyed a program of bridge and golf.

Westchester County

The handling of emergency calls and first-aid cases in Peekskill can best be taken care of by "your own doctor," declared Dr Robert Koop in a brief statement issued on July 30 on behalf of the Peekskill Medical Board.

The statement follows:

"The Medical Board agreed that the prompt, efficient care in an emergency can be assured only by your own doctor.

"In an emergency call him. If unavailable, his office will secure another physician for you."

The statement came as a result of a discussion among the doctors on the recent flare-up on the handling of emergency cases. Attention on this matter was focused by the Peekskill Lions Club following the drowning of a boy in the pool at Indian Point Park, when there was considerable delay in securing the services of a doctor.

The matter was recently discussed at a special meeting of the Medical Board of the Peekskill Hospital, and it was announced that a statement would be forthcoming shortly.

A spokesman for the group said he believed that the "plan," which had "always worked out satisfactorily in the past," would "work out well in the future."

VITAMINS GOING WILD

The public is warned in an editorial in the *New York Medical Week* that "unscrupulous salesmen of certain vitamin preparations" are canvassing housewives and making "the false assertion that they are making a survey for the Department of Health." The editorial points out that the department does not sponsor commercial sales and that it is not conducting a

survey relating to vitamin products. The editorial continues:

"The unsupervised sale of vitamin preparations has reached serious proportions even without this angle. Desirable is the addition of specific vitamins to deficient diets, there are grave dangers inherent in the indiscriminate use of vitamin concentrates."

SEPTEMBER 15, 1941

NUMBER 18

Editorial

We See by the Papers . . .

It is always a healthy thing to look about a little to see what others are doing and to ascertain what they are thinking about. Thus, we find in the *Bulletin of the Medical Society of the County of Westchester* for September, 1941, page 5, the following pertinent comment on the function of a medical society

It is wholly proper that any institution should occasionally have to set down in black and white, and publish for the world to see, its own reasons for being. The time has long past, if indeed it ever was, when individual physicians and their scientific societies could exist in a sort of economic vacuum untouched by the pressing social and economic issues of the day, untroubled by the problems incident to the helter-skelter mushrooming growth of the industrial and commercial civilization of our times. The spreading web of economic and social interdependence has now so thoroughly enveloped and entangled the institution of medicine that the medical society has perforce taken on many of the responsibilities of a trade guild. Paradoxically, if the medical society at this late hour were to return to its previous happy existence as an organization devoted solely to the development of the medical art, such an abdication of our responsibility in the social and economic spheres would immediately invite the encroachment of unsympathetic social forces to the extent that the professional independence and standards of the physician would ultimately be obliterated, and the integrity of medical art imperiled, if not destroyed.

So it is that we have taken on these new responsibilities and fulfilled these new functions, not possibly through any deliberate choice of our own, but because of an obvious compulsion to buttress and safeguard the scientific standards which once were our sole concern.

Concerning a medical society's public relations, the *Bulletin* has this to say

It has ever been our avowed and consistent theory that the true interests of the medical pro-

fession and of the public exactly coincide, and the converse of this proposition has been none the less dominant in our thinking—that the genuine public interest is and must continue to be the primary interest of the medical profession. Endowed with this enlightened philosophy, we have been able to carry on all our activities in full view of the public and we have welcomed, indeed sought, the assistance of the press and other media of public information in presenting our policies and viewpoints to the public.

The services which the medical society perform for the community are in essence the public relations policy of the society. These services earn for the society its truest and most important assets—namely, public esteem—public confidence in, and appreciation of, the aims and purposes of the medical organization. In the creation of such assets every physician in his own practice has a vitally necessary part to play. Every time a doctor visits a patient the public esteem of the medical profession is at stake. A thoughtless act on the part of the physician, an act of negligence or of inconsideration, the imposition of a fee that may reasonably be considered unreasonable, a crass word of disparagement passed upon another colleague, or simply a failure to do all for a patient that he feels should have been done for him—these or many other seemingly unimportant acts of commission or of omission may hurt the public relations of the medical profession far more seriously than we may realize.

A true public relations policy, like charity, begins at home.

The *A M A News* for August 14, 1941, calls attention to the rat as a disease carrier.

The growing health menace of the rat is pointed out in *Hygeia, The Health Magazine* for September by James Nevin Miller, Washington, D. C., who warns that "During the past four years rat-bite fever, also known as murine fever, has been spreading northward and inland from its former stronghold on the Gulf and southeastern coasts. This year it has invaded Washington, D. C., and while only 2 cases have been reported thus far,

*Special Article***Military Medicine in New York State Army Posts and Camps. II**

FOR the purpose of this article, your editors visited the station hospitals at Fort Wadsworth, Fort Jay, Fort Niagara, and Camp Upton. The station hospital at Fort Jay differs from those described in the first article of this series¹ in that in some ways it functions as a small general hospital. It serves not only the medical needs of the garrison stationed at Governors Island but also the adjacent metropolitan area and occasionally the entire corps area as well. In addition to the services usually found in the ordinary station hospital, an obstetric service is included. Acute venereal cases are referred to Fort Hamilton for treatment. An active service in general medicine and surgery and the specialties, with the exception of venereal diseases, is afforded.

Camp Upton and Fort Niagara contain the reception centers for their respective areas. Here, accepted draftees are sent for vocational testing, classification, outfitting, and inception of initial training. This function of these stations necessitates facilities in addition to those of the ordinary station. The men are cared for by the medical officers who have been assigned to the reception centers. Draftees remain at these centers for varying lengths of time, which results in a fluctuating strength of draftee personnel. The hospitals at the posts where the reception centers are located care for the occasional serum reactions that are encountered in the process of immunization in addition to the ordinary run of acute infections and injuries. The incidence of venereal disease is likely to be slightly higher than at posts that do not function as reception centers. Under the present Pre-Induction Examination Plan, men are examined by the Army Induction Boards one month prior to induction and have this interval of time to put their civil affairs in order. During this period they are not under military discipline, and the incidence of venereal disease is not amenable to control. Men occasionally report with infections acquired after completion of the physical examination by the Induction Board.

Your editors found excellent cooperation between the military and civil medical authorities and indications of constructive efforts being made to handle the problem of venereal

disease. All cases are immediately reported by the post hospitals to the local health officials with as much factual data concerning the exposure as can be obtained. Action by the public health and local police authorities then follows to remove local sources of infection.

In the station hospitals visited, many changes are being made in storage, preparation, and serving of food in order to obtain greater efficiency. Some buildings, now used for hospitals, were not designed originally for that purpose, while others were intended to serve as hospitals for a much smaller personnel. The reallocation of space to conform to modern practice, with new equipment, painting, redecorating, and building, is going forward at a rapid rate. Medical officers' quarters are comfortable, most hospitals having lounging rooms with radio, piano, and both popular and scientific magazines. A circulating library system passes the current issues of medical journals along from station to station for the information of the officer personnel at each hospital. Classes for instruction in paper work are being organized.

Young Medical Reserve officers, accustomed to serving on the staffs of civilian hospitals where the housekeeping and accounting details are separate from medical administration, in the Army are confronted with the necessity of knowing and performing both medical and administrative duties. The latter are varied, requiring a knowledge of regulations and forms and involving accountability for property of many kinds. Medical Reserve officers may not take much interest in acquiring these details, even though courses in instruction are offered, thinking that the knowledge will be of little benefit to them when they return to civil life. On the other hand, there is presented a real opportunity in these courses of instruction for many to acquire fundamental and highly useful knowledge of hospital administration. The medical officer with a working knowledge of Army Regulations and the ability to do administrative work is in great demand.

Most of the station hospitals that we have visited are located within a reasonably close distance to the headquarters of some county medical society. The majority of the medical officers are members of their own county society and might participate, if the demands of the service permit, in the scientific sessions

¹ Editorial—Special Article. New York State Med. J. No. 15, 1525 (August 1) 1941.

the potential menace to the entire nation of this destroyer of health can scarcely be exaggerated.

This animal [the rat] is the world's most notorious disease carrier, with perhaps two exceptions, the tick and the flea. And when it is realized that the rat, in addition to its own ability as a carrier, is often infested with both of these death-dealing agencies at the same time, its true worth as a human health menace is fully appreciated.

No less than seven major diseases and illnesses are known by medical science to be transmitted or caused by rats and almost a dozen more are under suspicion. Besides bubonic plague and typhus fever, the list includes pneumonic plague, jaundice, parasitic mange, tapeworm, and perhaps foot and mouth disease.

Fortunately for the health of the nation, most big cities now have a police regulation requiring citizens to keep garbage and trash containers tightly closed.

Fumigation with hydrocyanic acid gas is the Public Health Service's most effective means of reducing a large rat population aboard ships. In this connection two new pieces of equipment have been developed. One is a pump which forces the gas into the tiniest rat harborages. It can be operated easily by one man. The other apparatus is a more efficient type of gas mask that affords the fumigator foolproof protection against the life snuffing fumes of the poison.

In view of the haste with which ships carrying war supplies are now being loaded and unloaded in our ports it is possible that the rat may become a greater factor than in normal times in disease dissemination. In this regard it would be well to note carefully the release from the U S P H printed on page 1818 which tells of a conference on the subject of domestic plague.

Demands on U S physicians will be greater shortly when the total war pattern develops, says *Medical Economics* for August, 1941, page 34.

At present, the effort to coordinate America's medical resources is almost unbelievably complex. It is equally slow-moving. Reason: Authority to do the job is split up between the army, navy, Public Health Service, Selective Service, the A M A, and many lesser government and civilian agencies. This may be good democracy. But defense officials pointedly complain of its inefficiency for emergency planning.

The major snarls produced by emergency health needs eventually wind up in the Washington office of the Health and Medical Committee. The committee is the chief advisory agency on medical preparedness plans. It functions under Federal Security Administrator Paul V. McNutt, who is coordinator of Health, Welfare, and Related Defense Activities.

In last month's action, the Health and Medical Committee recommended creation of the Procurement and Assignment Agency for Medical Personnel in a formal report to Coordinator McNutt. As the next step, McNutt will meet with War and Navy Secretaries Stimson and Knox to lay out an actual blueprint of the new agency's framework.

Official operation of the agency must await Congressional legislation. Hence its establishment is not likely before two or three months—perhaps more—have passed. Meanwhile, the plan is to be perfected for immediate use in the event of a national crisis.

The editors of the *Tennessee Medical Journal* for August, 1941, raise a very pertinent question in an editorial. We quote:

The attempt has been made to propagandize the public with the idea that the democratic system of medical care is very defective and that something radical should be done about it by the state and national governments.

Statistical data as to the rejections of draftees for military service are given as a reason.

It might be worth while to inject this one thought into the question at this time. During the more than twenty years that have intervened since World War No. 1 there has been a very great increase in the amount of medical care rendered by various branches of government in the United States.

Appropriations for health and medical care activities by federal, state, county, and municipal governments have been multiplied many times over again. These agencies and activities have entered into the field of infant care, maternity care, school health, public health, tuberculosis, crippled children—in fact, every branch of medical care has been touched by appropriations and by agencies.

It is appropriate to raise the question as to whether all these expenditures and agencies have yielded results commensurate with the expenditures made.

If by "results" the editors mean jobs, the results seem somewhat commensurate. If they are speaking of "health," we refer them to the Selective Service authorities for data on eyes, teeth, or what have you.

Symposium on Spastic Paralysis

THE CEREBRAL PALSY PROBLEM

LYMAN C. DURYEA, M.D., New York City

WHEN the average person thinks of crippling conditions he almost invariably thinks of poliomyelitis. But poliomyelitis accounts for 20 per cent only of crippling conditions in children under age 21. The second greatest major cause of crippling is seldom considered. The medieval conception that crippling is evidence of a family curse, of guilt, or of a tainted family strain and so to be concealed may be one reason why cerebral palsy receives so little attention. Cerebral palsy is the second greatest individual cause of crippling, a fact that is surprising even to many of the medical profession.

In the United States there are known to be at least 19,000 children with cerebral palsy, and the total is estimated to be nearer to 35,000. In New York City there are known to be about 2,000 children under age 21 who have cerebral palsy. The annual incidence in New York City is at least 0.0015 per cent of all infants born, excluding stillbirths and neonatal deaths. The incidence of cerebral palsy bears an apparent relation to the birth rate, although not necessarily a causal relationship, and it is not subject to epidemiologic fluctuations. These figures for New York City exclude those known to be feeble-minded. The prevalence of cerebral palsy is said to be the same for urban and rural areas. This is set at about 50 cases per 100,000 of the total population. The annual case load can be estimated with reasonable accuracy, and definitive programs of research and treatment can be instituted once the problem is made apparent.

Most cities in the country are not aware of the extent of the problem and of the numbers of children involved. Few cities have officially established adequate treatment or educational facilities for children with cerebral palsy. Private facilities are limited. As a result the majority of children with cerebral palsy receive little or no treatment.

In sixty-one cities, interested medical groups have instituted research and treatment pro-

grams where selected groups of these children are receiving intensive treatment and concurrent education.

In general, little is being done in the elementary or high schools toward the physical rehabilitation of these children, and few teachers are available who are trained in the special educational techniques required. The most severe cases are almost totally neglected with the exception of those who receive some instruction in their homes by visiting teachers who provide training. The more severely handicapped children with cerebral palsy require special educational techniques. There is little concerted effort made to supply these techniques or to correlate instruction programs with muscle re-education and training programs. Special educational techniques have to be developed on an individual basis, since the education of these children requires much ingenuity because of the existence of multiple physical difficulties.

The teaching of these children is closely associated with their treatment and training. For the integration of the two, there are required teachers who have the proper psychological approach, who are patient, and who are trained in the special techniques. There are no facilities for the selection and training of these children except those available in the centers and institutions where this special work is being done.

About 70 per cent of all children with cerebral palsy are stated to have an I.Q. of at least 70 and are therefore considered educable. In a small group in a clinic day school in New York City the I.Q.'s ranged from 74 to 142. Of those with an I.Q. of 70 or above, many can be made economically self-supporting and others can be trained to care for their personal needs.

Neither the problem nor its extent have received adequate attention by the medical profession.

Most hospitals treat some cases of cerebral palsy in physical therapy departments. Rarely in these departments are there technicians trained in the special techniques necessary, and there are few hospitals that have

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 30, 1941.

Director, Crippled Children's Division, Department of Health.

of these local societies to the benefit of everybody In this connection, any statements made by an officer would be based on his personal opinion, and articles may not be published without the prior approval of the Surgeon General Members of local county soci-

eties would be afforded the privilege of personal contact with many of the younger men from different parts of the state and medical officers would be afforded the opportunity of participation in the programs carried on by the county societies

Plague Control Conference*

Evidence that plague infection among wild rodents of western United States is spreading eastward prompted Surgeon General Thomas Parran of the United States Public Health Service to call a plague control conference August 28-29 at Salt Lake City, Utah

The conference was attended by health officers from California, Oregon, Washington, Nevada, Montana, Idaho, Wyoming, Utah, Colorado, Arizona, New Mexico, and North Dakota Infection among wild rodents has progressed steadily during the past five years from the Pacific Coast eastward as far as the Dakotas The purpose of the conference was stimulation of rat control programs in urban and rural areas

In the past, outbreaks of human plague have almost invariably been preceded by marked increase in the disease among animals which harbor the infection Plague is passed from rodents to humans by infected fleas Accord-

ing to Surgeon General Parran, unless prompt and effective control measures are undertaken plague infection among rodents may spread to the more populous areas of the Middle West and East creating a serious hazard to humans

Surveys conducted by the Public Health Service in 1935 revealed plague infection among wild rodents in Montana, California, and Oregon In each succeeding year, including 1941, infection has been demonstrated in ground squirrels, chipmunks, rats, marmots, and other wild rodents in Arizona, California, Idaho, Montana, Nevada, New Mexico, Utah, Washington, and Wyoming

Infection among rodents has been discovered recently as far east as North Dakota

The first outbreak of human plague in this country occurred in 1900 in San Francisco Plague in California reached epidemic proportions in 1907-1908 Since 1900 there have been 502 cases and 315 deaths in this country Two human cases of plague, both in California, have been reported this year

*Release from The Federal Security Agency, U S Public Health Service, Washington.

SCIENTIFIC EXHIBITS

1942 Annual Meeting

Applications for space for the scientific exhibits should be made directly to

Dr J G Fred Hiss,
505 State Tower Building,
Syracuse, New York,

Chairman of Subcommittee on Scientific Exhibits of the Convention Committee

The Annual Meeting will be held April 27-30, 1942, Hotel Waldorf-Astoria, New York, New York. The list will be closed on January 1, 1942

PETER IRVING, M D, Secretary

treatability whether or not they are to be referred for treatment. The classification serves as a means of selecting children for treatment and as a measure of the extent of the total problem. The classification for treatment purposes should be uniform. Consideration should be given to the limitations in the scope of a specific local program. For every child, prior to selection for treatment, a history and record regarding the child's present status should be prepared.

There should be selection of children for referral to treatment facilities which may be classified as follows:

- 1 Hospital resident treatment for the more severely handicapped

- 2 Outpatient clinic treatment for the less severely handicapped who are adjustable in the regular schools

- 3 Hospital clinic day school treatment for the intermediate group and for those whose major difficulty is a repulsive appearance. Here intensive treatment can be carried out concurrently with education during certain hours of the day.

- 4 Special training and treatment facilities as required for special disabilities

- 5 Home training and parental education in home training for home-bound children and others to provide continuity of the treatment instituted in hospitals and clinics

Hospital resident treatments should provide maintenance, schooling, medical care, entertainment, and recreation, in addition to treatment of the specific disabilities. The more severely handicapped children should be accepted for treatment in resident units for a trial period of three months. This period should be extended if the child's progress warrants it or until further treatment is considered inadvisable or unnecessary.

Children should be selected in the diagnostic clinic for treatment in outpatient clinics. Preferably, only those children who offer a reasonably good treatment prognosis should be selected for treatment in the clinic. Because of the large case load in the older age groups it is advisable to limit temporarily the provision of facilities. As experience develops, such facilities should be gradually expanded to meet the needs of all eligible children with cerebral palsy with an I Q of 70 or above.

Hospital clinic day schools for selected children are important. In clinic day schools intensive treatment should be given concurrently with instruction. Children who require intensive treatment and training should be selected in the diagnostic clinics for treatment

in these schools on the basis of the degree of physical defect and the severity of multiple handicaps.

A program of home training and care should be instituted by the utilization of the services of local orthopedic and other nursing agencies. An essential part of care is the training and education of the parents in their responsibilities to the child and in the specific procedures that the parents should follow in the home to supplement the treatment and training provided the children by private physicians and clinics.

The orthopedic nursing agencies and the social agencies have great opportunities in the fields of general care and supervision, in parental education, and in the provision of follow-up services and the solution of socio-economic problems.

A program of follow-up to determine treatment status should be instituted in order that a child may progress from one type of service to another as his condition warrants.

The basic personnel required for a properly established diagnostic and treatment program consists of:

- 1 A physician experienced in the diagnosis and treatment of cerebral palsy

- 2 A psychologist with special experience in examining children with cerebral palsy

- 3 A chief physical therapist trained and experienced in the treatment of cerebral palsy and capable of training others

- 4 An assistant physical therapist with similar qualifications

- 5 Teachers experienced in teaching children with cerebral palsy

This personnel should be utilized to provide to others training and education in diagnosis and treatment of cerebral palsy and in the special techniques required. Research should be encouraged.

Conclusion

In order to meet effectively the problem of cerebral palsy:

- 1 There should be established facilities for research into its causes, prevention, functional pathology, and treatment

- 2 Information concerning current methods of treatment and education should be disseminated

- 3 Facilities for the treatment of cerebral palsy should be established in acceptable hospitals and should provide for medical, neurologic, and orthopedic supervision, social service, corrective physical education, and psychometric testing

clinics especially for the treatment of cerebral palsy where the necessary technics are carried out by properly trained personnel

The problems of individual children with cerebral palsy are the resultants of associated multiple handicaps. They are different and more difficult of solution than those of any other type of handicapped children.

In the recent past it was generally considered that nothing could be done for these children. In the past ten years considerable progress has been made in methods of treatment and training so that at present there is opportunity, based on experience, to approach the therapeutic problem intelligently. The problem in regard to the provision of facilities for treatment is not insurmountable.

The following are required

- 1 Research into the causes, prevention, functional pathology, and the treatment of cerebral palsy. It is proper that these be the responsibilities of orthopedists and neurologists.

- 2 The institution of adequate and proper hospital and clinic facilities.

- 3 The institution of more adequate educational procedures based on individual requirements resulting from multiple handicaps.

Current knowledge of methods of diagnosis, treatment, and training should be made available to the undergraduate medical students, to interns and residents, and to the medical profession. Nonprofessional personnel should be trained in the special technics that come within their fields. Educators should be trained in the special educational technics required, with consideration of the existence of multiple handicaps so common among children with cerebral palsy.

Almost all children with cerebral palsy have the condition at the time of birth or soon thereafter and can usually be diagnosed by the age of 1½ to 2 years, although some of the multiple handicaps may not be diagnosed until later. Many of those who are treating cerebral palsy believe that the condition should be treated early in life. Only a relatively small proportion of these children in the age group under 5 years are under the supervision of hospitals or physicians. This indicates the need for early case-finding. When children reach the age of 5 or 6, parents become concerned about their education, and hospital records show that larger numbers of children in each of the older childhood ages are under supervision than is true of those under 5 years of age.

There is a large reservoir of children over

age 5 for whom little has been done. This group contains the increment of all the unsuccessfully treated cases and those who have had no treatment and whose original handicaps have been permitted to develop untreated. The number of children in this group is comparatively large. It would appear, for economic reasons, that the approach to the current problem should be through the group under 5 years of age to study methods of decreasing ultimate handicaps and, thus, eventually to lessen the load in the older age group. An adequate program necessitates consideration of both age groups in research and treatment. There should be diagnostic facilities for selecting children with cerebral palsy who offer a reasonable prognosis of treatment and education. Proper selection of children for treatment is essential. This can be done best by diagnostic clinics where the specialist in cerebral palsy and the psychologist make a determination of the treatment prognosis for each case. The treatment prognosis is the criterion upon which children in the older age group should be selected for treatment. The younger children, under age 5, should probably be blanketed into a treatment program because, as a group, they probably offer a better ultimate treatment prognosis.

Diagnostic clinics should be an integral part of established cerebral palsy clinics, staffed by members of the clinic staff. The diagnostic functions should be distinct from the therapeutic functions. The frequency of the diagnostic sessions should depend upon the case load of individual communities and the case load of individual hospitals. The number of children per diagnostic session should be limited on an appointment basis.

The examinations in the diagnostic clinics should include

- 1 A complete physical examination to determine the type of disability, the cause, extent and degree, the treatability, and the treatment prognosis.

- 2 A mental examination to determine the social maturity, level of intelligence, stability, and educability. The I Q examination should always follow a complete physical examination so that the psychologist making the tests can be acquainted with all of the defects. The tests should be given with the modifications required by the existing sensory defects. The results of these tests when indicating subnormality should not be accepted as final, since no test is entirely satisfactory for children with cerebral palsy.

Children should be classified in terms of

TABLE 1—SUMMARY OF DIFFERENT TYPES OF PARALYSIS

Normal	Involuntary Movements	Tendon Reflex	Opposed Muscles Relax	Motor Unit Management	Treatment
	None	Short, moderate		Asynchronous	
Lower neuron palsy	None	Abolished	Relax		Support graded exercise
Paraplegia, acute	None	Abolished	Relax		Support care of bladder and back
Chronic	Rare ? reflex	Spreads widely	May relax or contract	Synchronous	Care of bladder posterior root section?
Pyramidal tract lesion	Reflex or none	Low threshold violent, sustained	Relax	Synchronous	Retraining posterior root section?
Rigidity	None	"	Contract	Synchronous	{ Hyoscine, etc., pyramidal tract section, cortical resection Extrapyramidal tract section, cortical resection anterior root section
Alternating tremor	Alternating	"	Relax	Synchronous	
Athetous dystonia torticollis	Slow irregular	Varies	Contract	Asynchronous	

causing one or another group of fibers to suspend contraction usually before any discomfort reaches consciousness

Paraplegia—When the spinal cord is abruptly divided (for example, by an acute thrombotic transverse myelitis or following a fracture of the spine), the phenomenon of "spinal shock" occurs. The activity of the anterior horn cells is abruptly suppressed below the level of the lesion, so that a complete flaccid paralysis results resembling that seen with severe polyneuritis. This condition lasts days or weeks and indefinitely if the patient develops a cystitis, decubitus, or other inflammatory disease.

The treatment of spinal shock consists chiefly in preventing infection. The most important step is the installation of tidal drainage of the bladder,⁷ which should be done immediately and routinely in every case. Care of the back then becomes much easier. The administration of mandelic acid or of sulfathiazole (1 Gm. q 4 hours) should be commenced at the first suggestion of bladder infection.

The care of the extremities during this period consists chiefly of preventing foot-drop or other muscular lesions, of the use of a cradle, and of massage to maintain the nutrition of muscles.

When spinal shock passes off, a stage of hyperreflexia sets in. If the transection of the cord is complete, the legs are usually relaxed except when some trifling stimulus—such as is produced by stroking the skin—reaches the isolated spinal segment, when a "mass reflex" occurs. The legs flex on the abdomen and, often, urine and stools are discharged.

Often, however, a variable number of fibers still pass the site of injury. The patient then has a slight control over the legs, bladder, or bowel and some sensation—usually disagree-

able—from the lower part of the body. The condition of the muscles varies, but they are often constantly or intermittently in a state of strong contraction, which opposes voluntary movement or produces athetoid tremors.

This distressing condition is difficult to treat. The involuntary spasms are often stirred up by intestinal movements or chilling of the skin, of which the patient is unaware. Attention to "discomforts" that the patient does not perceive may palliate them. The bladder may become spastic and contracted, in which case considerable relief may be afforded by occasional courses of tidal drainage under relatively high pressure. Bromides have a slight effect.

Surgically, tenotomies and peripheral nerve sections are standard practice. The use of posterior root section (first practiced by Dana and Abbe, members of the Medical Society of the State of New York), is often extremely successful in well-chosen cases of this group. The reasons for the undeserved disrepute of this operation will be considered below. It is possible that some procedure directed at intraspinal pathways would afford relief, but experiments in this direction have so far been fruitless.^{8,9}

Hemiplegia, Monoplegia—Injury to the pyramidal tract anywhere in its course produces a hyperreflexia and the appearance of the Babinski, Hoffmann, and other pathologic reflexes (as soon as "spinal shock" has passed off). Whether or not there is a superimposed rigidity depends upon factors that are obscure. With or without it, the condition is usually called "spasticity," even though the extremity may be entirely relaxed in certain positions.

The disability resulting from hemiparesis is in part dependent upon the abnormal pull of antagonists which opposes any movement as

4 Such facilities should include diagnostic facilities, and there should be specific recommendations made for treatment

5 Facilities should be developed in such a manner as to permit of scientific study and research into the general problems of the causes and treatment of cerebral palsy

6 Selected children should receive physical training and education in hospital clinic day schools or in inservice hospital units so that they may receive physical education concurrently with their scholastic education

7 Facilities for the treatment of cerebral

palsy should include provision for the training of personnel in the technics of diagnosis and treatment

There is an increasing recognition of this problem of children with cerebral palsy as evidenced by the fact that, in twenty-seven states, programs are in operation on a limited scale under private and public auspices out of which, in time, should come experience that will provide guidance for more adequate programs

No community should neglect these children any longer

NEUROLOGIC ASPECTS OF SPASTICITY AND ATHETOSIS

TRACY J PUTNAM, M D, New York City

TYPES of Palsy—The fundamental unit of the neuromuscular system consists of a single anterior horn cell, its axon, and the group of muscle fibers which it innervates. If any part of this structure is destroyed (by poliomyelitis, trauma to the nerve, or "toxic" or deficiency states), a flaccid palsy results. The principles of treatment of such palsies are well known—they consist in preventing overstretching of the weakened muscles and exercises, apparatus, or operations to compensate for the defect if spontaneous recovery does not occur.

The paralyzes and other disorders due to disease of suprasegmental long spinal tracts and higher structures are often lumped together as "cerebral palsies" or "spasticity," when as a matter of fact the variety of physiologic conditions that may exist alone or in combination is enormous. Relatively little special attention has been given to the treatment of these conditions. Often the same treatment is given as to cases of poliomyelitis, and almost no attempt has been made to apply physiologic knowledge in treatment. This is, of course, in part because the physiology and clinical manifestations of many of the syndromes have been obscure. Recent investigations have considerably clarified the problem and have provided a firmer basis for rational treatment.

The data that have been most illuminating are

1 More precise descriptions of the results of stimulation and extirpation of definite

cerebral structures in primates (reviewed in Fulton's book¹)

2 A study of the various syndromes by means of the extremely clear and definite method of electromyography (Hoefel and Putnam^{2,3} and Hoefel⁴). A schema of the results of this study is shown in Table 1.

3 Observations resulting from an increasing range of neurosurgical operations for the relief of spasticity, tremors, rigidity, and athetosis (reviewed in the symposium published by the Association for Research in Nervous and Mental Disease on "The Basal Ganglia"⁵).

The normal neurologic management of motor performance will be considered below, then that of various fairly definite syndromes, with suggestions for the treatment of each. It should go without saying that combinations of syndromes are often encountered.

Normal Neuromuscular Management—It has become clear, chiefly through the work of Sherrington and his co-workers⁶ in animals and that of Hoefel^{2,3,4} in human beings, that not only active contraction of muscles to produce work, but also the involuntary and unconscious "tone" that maintains posture, is produced by the intermittent contraction of motor units (of which there are many thousands in the smallest muscles). In either volitional or "tonic" contraction, single motor units twitch briefly but repeatedly in combination and a sort of irregular asynchronous rotation, which produces the effect of a smooth flow of force like the explosions in a gasoline engine. This partitioning of activity is regulated, to some extent at least, by sensory impulses, arising perhaps as a result of fatigue,

Read at the Annual Meeting of the Medical Society of the State of New York, Buffalo, New York, April 30, 1941.

causing one or another group of fibers to suspend contraction usually before any discomfort reaches consciousness

Paraplegia—When the spinal cord is abruptly divided (for example, by an acute thrombotic transverse myelitis or following a fracture of the spine), the phenomenon of "spinal shock" occurs. The activity of the anterior horn cells is abruptly suppressed below the level of the lesion, so that a complete flaccid paralysis results resembling that seen with severe polyneuritis. This condition lasts days or weeks and indefinitely if the patient develops a cystitis, decubitus, or other inflammatory disease.

The treatment of spinal shock consists chiefly in preventing infection. The most important step is the installation of tidal drainage of the bladder, which should be done immediately and routinely in every case. Care of the back then becomes much easier. The administration of mandelic acid or of sulfathiazole (1 Gm q 4 hours) should be commenced at the first suggestion of bladder infection.

The care of the extremities during this period consists chiefly of preventing foot-drop or other muscular lesions, of the use of a cradle, and of massage to maintain the nutrition of muscles.

When spinal shock passes off, a stage of hyperreflexia sets in. If the transection of the cord is complete, the legs are usually relaxed except when some trifling stimulus—such as is produced by stroking the skin—reaches the isolated spinal segment, when a "mass reflex" occurs. The legs flex on the abdomen and, often, urine and stools are discharged.

Often, however, a variable number of fibers still pass the site of injury. The patient then has a slight control over the legs, bladder, or bowel and some sensation—usually disagree-

able—from the lower part of the body. The condition of the muscles varies, but they are often constantly or intermittently in a state of strong contraction, which opposes voluntary movement or produces athetoid tremors.

This distressing condition is difficult to treat. The involuntary spasms are often stirred up by intestinal movements or chilling of the skin, of which the patient is unaware. Attention to "discomforts" that the patient does not perceive may palliate them. The bladder may become spastic and contracted, in which case considerable relief may be afforded by occasional courses of tidal drainage under relatively high pressure. Bromides have a slight effect.

Surgically, tenotomies and peripheral nerve sections are standard practice. The use of posterior root section (first practiced by Dana and Abbe, members of the Medical Society of the State of New York), is often extremely successful in well-chosen cases of this group. The reasons for the undeserved disrepute of this operation will be considered below. It is possible that some procedure directed at intraspinal pathways would afford relief, but experiments in this direction have so far been fruitless.

Hemiplegia, Monoplegia—Injury to the pyramidal tract anywhere in its course produces a hyperreflexia and the appearance of the Babinski, Hoffmann, and other pathologic reflexes (as soon as "spinal shock" has passed off). Whether or not there is a superimposed rigidity depends upon factors that are obscure. With or without it, the condition is usually called "spasticity," even though the extremity may be entirely relaxed in certain positions.

The disability resulting from hemiparesis is in part dependent upon the abnormal pull of antagonists which opposes any movement as

soon as it is begun. In part, it is due to a loss of the exquisite blending and grading of motor unit discharge characteristic of normal movement. This is well shown by electromyography, the motor units are seen to discharge in intermittent volleys, producing an irregular, tremulous, and inefficient movement. Finally, atrophy of disuse takes place.

The treatment of hemiparesis is not well standardized. In the acute, flaccid stage, the patient can sometimes be "reminded" how to use his extremities by a session or two of faradic stimulation. Aside from this, electrical stimulation is wholly useless in the treatment of suprasegmental paralysis (as in peripheral nerve disease, Chor¹⁰). The patient should be encouraged to practice using the extremity and should be given some occupational therapy that will use his remaining powers to their best advantage. Massage should be avoided after the stage of shock, since it tends to arouse proprioceptive reflexes. Passive motions carried out slowly so as not to be stimulating, should put the joints through a full range of motion daily. Splints are of little use, except that a caliper splint hinged at the ankle may be a great comfort as a remedy for foot-drop.

Orthopedic operations are helpful in selected instances. Posterior root section or subarachnoid injection of alcohol (carried out with due caution) is theoretically sound and often helpful if segmental reflexes or hyperreflexia constitutes a substantial part of the disability.

Rigidity—Rigidity differs from hyperreflexia or spasticity by the fact that there is a constant innervation of both agonists and antagonists, which are practically never at complete rest. This is clearly shown by electromyography. The proprioceptive (tendon, stretch) reflexes are usually somewhat exaggerated also.

Rigidity is seen in its purest form as a part of the parkinsonian syndrome. It may be associated with birth injuries or other diffuse lesions of various types. The location of the lesions essential to it is obscure (Aring¹¹ and Balser¹²).

Therapeutically, the problem is chiefly one of relaxing spasm, since strength is often well preserved. In parkinsonian cases, drugs of the atropine series are often successful. The new Bulgarian belladonna seems to have especial virtue in some cases. Physical therapy and psychotherapy do not seem to accomplish much. Certain operations on the nervous system have been tried,⁵ but the results are not yet certain. Peripheral nerve sections and posterior rhizotomy do not seem

to accomplish much toward relieving the syndrome.

Alternating Tremor—The most familiar form of tremor is that often seen in post-encephalitic states. The tremor has a definite rate and rhythm of 5 to 8 per second, which varies little in a given case. It is produced by a brief twitch of one muscle, then a twitch of its antagonist, both unopposed. As a result, little energy goes into the movement, and the "basal" metabolism is usually normal or low.¹³ Lesions are found characteristically in the striatum and substantia nigra, not interrupting either pyramidal or extrapyramidal pathways (Fig. 1).

As with rigidity, the most widely useful treatment is the use of drugs of the atropine group. There is often an associated arthritis and peri-arthritis, for these, massage is useful, but not for the tremor. Physical therapy in general accomplishes little.

A promising start toward an effective surgical treatment of severe cases of tremor has recently been made. The procedures employed have included cortical operations (Bucy¹⁴ and Klemme⁶), section of the pyramidal tract in the spinal cord,¹⁵ and operations on the basal ganglia (Meyers⁶). Probably all of them produce a greater or less injury of the pyramidal tract but surprisingly little disability. The operative results have been brought together in the symposium of the Association for Research in Nervous and Mental Disease, already mentioned.⁵ It is too early to say which type of operation will prove the most conservative, but the proportion of relief has been high with all of them. Following operations of this type, patients have sometimes returned to work. Ordinarily, walking is improved, and the affected hand becomes useful for eating, writing, etc. Such operations may be satisfactorily applied to perhaps the majority of severe unilateral cases, but the feasibility of their employment in bilateral cases is at present in some doubt.

Athetosis—This term was first used by Dr. W. A. Hammond (a member of the Medical Society of the State of New York) to describe a syndrome consisting of involuntary, irregular, slow, squirming movements of one limb appearing in an adult after a hemiplegia. Physiologically, the squirming and intermittent rigidity is produced by irregular, variable contractions of many or all of the muscles of an extremity, sometimes one and sometimes another predominating.

A similar disorder sometimes begins in infancy or early life and attacks the muscles of

FIG 1 Diagram of the path of the pyramidal tract and of the extrapyramidal system (schematic). Note the position of the extrapyramidal tracts in the anterior column of the spinal cord, also note that there is at least one intercalated neurone between the ending of the long tracts and the anterior horn cell. Intersegmental short spinal tracts are not shown.

the trunk as well as the extremities. It is then usually known as dystonia. Torticollis, chronic chorea, and hemiballism are other sub-varieties of the syndrome. Lesions are regu-

larly found in the caudate and lenticular nuclei, apparently interrupting certain links in the extrapyramidal chain (Fig 1). The central mechanism is obscure, but it seems

fairly clear that the abnormal impulses do not utilize the pyramidal tracts exclusively (perhaps not at all), for the dyskinesia may occur even when there is a complete loss of voluntary control and, anatomically, a degeneration of the pyramids may be found.

Attempts at treatment of athetosis and dystonia, considered hopeless until recently, are now proceeding in three directions. Retraining and careful minute instruction in walking and the use of the hands often produce considerable improvement, chiefly in the milder cases. Attention to providing special chairs, tables, typewriters, etc., may make a great difference in the patient's comfort.

The use of drugs of the curara series has aroused a good deal of interest. At present, however, the treatment cannot be considered a practical one, for proper preparations are not to be had. Whether the benefits will ever outweigh the difficulties and dangers of the treatment remains to be seen.

Finally, there has been great progress in surgical treatment (which, however, is less satisfactory in this group of diseases than in cases of alternating tremor).

As with tremor, operations have been performed at the cortical⁶ and at the spinal level. Either may produce satisfactory results in a certain proportion of cases, but disappointments are common with both. The cortical operations are on the whole safer, but they carry more danger of producing motor disability. The recently devised method of operation under local anesthesia and injection of procaine into the cortex before any extirpation is carried out should improve results.^{8,13} The spinal operations (on the extrapyramidal pathways in the anterior column) are more suitable for dystonic and bilateral cases and also those complicated by torticollis.¹⁴

Posterior root section is not effective. Curiously enough, it was the failure of posterior root section in cases of athetosis which caused Frazier to throw the weight of his authority against the use of the operation. In addition, he alleged that the mortality of laminectomy was too high to justify its use except where life is at stake and that spastic children are poor subjects for operation. Scarcely a single neurologic surgeon would agree with these statements today.

Spasmodic Torticollis.—This is a peculiar subvariety of dystonia, attacking the muscles of the neck and shoulders chiefly or exclusively. There is considerable doubt as to the nature of the disease, some cases appear to have been relieved by psychotherapy,¹⁵ but others have

undergone extensive treatment without improvement. In some cases, further, there are many manifestations of dystonia elsewhere in the body, and lesions have been found post-mortem.¹⁵ The condition is a most distressing one, and patients often beg urgently for relief.

The problem of ruling out a hysterical origin for the spasm is one that deserves first consideration. Some progress has been made toward a positive diagnosis of hysteria by means of the Rorschach test. True neurotic disturbances should disappear with relatively light anesthesia (e.g., with pentothal). In cases of torticollis in which mechanical or surgical treatment is in prospect, it is probably wise to refer the patient to a psychiatrist for a trial course of treatment before any radical procedure is undertaken. In general, hysterical symptoms yield rather rapidly to suggestion and, on the other hand, a patient who is really miserable from his torticollis will demand a radical treatment rather promptly if he knows that it exists.

Since medical and orthopedic treatment are seldom curative in torticollis, the effective type of operation introduced by Foerster¹⁶ and modified by Dandy¹⁷ and others^{18,19} has been a great boon. It consists in a bilateral section of the first three cervical anterior roots and the spinal accessories in the posterior fossa, if they can be easily reached, on both sides. If the accessories cannot be reached intraspinally, they are divided in the neck at a second stage. The fourth anterior root may also be taken in severe cases.

The results of this operation have been uniformly good. The patient retains a surprising mobility of the neck. No deaths have been reported. The pessimism often expressed in regard to the surgical treatment of torticollis is a relic of the era of myotomies and extra-spinal operations, which are indeed useless.

Conclusions

Proper treatment of spastic disorders and dyskinesias should rest upon a knowledge of the fundamental physiologic mechanisms at work. Our knowledge of these mechanisms has greatly improved in recent years, and certain therapeutic principles naturally follow. The next few years should show a considerable harvest from them.

Summary

1 The diseases of the peripheral neuromuscular unit, such as poliomyelitis and neuritis, are fairly well understood, and forms of treat-

ment are standardized. This is not true of the paralyses due to diseases of tracts of the spinal cord and higher structures.

2 The important steps in the care of acute paraplegia are the use of tidal drainage to prevent infection of the bladder and care of the skin. In the chronic stage with spasticity, hyperreflexia, and involuntary movements, meticulous care of the bowels and avoidance of chilling or irritation of the skin are advisable. Posterior root section is sometimes of value.

3 In cases of hemiplegia, retraining is often helpful. Massage and the use of electricity are usually to be avoided. Posterior root section is occasionally indicated.

4 Rigidity (for example, as a part of parkinsonism) is best treated with drugs of the atropine series, although successful results of surgical treatment have been reported.

5 Alternating tremor also responds to treatment with belladonna and the like. Various surgical operations (directed chiefly at the pyramidal tract) have yielded a large proportion of satisfactory results in severe unilateral cases, with a low mortality.

6 Athetosis and dystonia are often benefited by retraining. Several neurosurgical procedures are available and are sometimes strikingly beneficial, but the results are more variable than those following the operation for alternating tremor.

7 Spasmodic torticollis is a fairly definite entity, which may, however, easily be confused with hysteria. Psychotherapy is usually

worth trying, but, if it fails, the Foerster-Dandy operation of intraspinal anterior rhizotomy gives excellent results without reported mortality.

8 The differentiation of these various conditions and the decision as to treatment often demand thorough neurologic study, which should include electromyography in doubtful cases.

THE DIFFERENTIAL CHARACTERISTICS OF SPASTICITY AND ATHETOSIS IN RELATION TO THERAPEUTIC MEASURES

WINTHROP MORGAN PHELPS, M.D., Baltimore

CEREBRAL palsy is a complicated group of conditions. The name cerebral palsy refers to the motor manifestations, probably because these are the most obvious. They are also frequently the most misleading. The importance of the condition in the fields of pediatrics, neurology, neurosurgery, psychology, and education, as well as orthopedics, is great. It is difficult to discuss cerebral palsy without relating it to all these fields.

The condition is widespread and apparently quite even in its distribution between cities and rural areas. Surveys, some complete

and others still in progress, have shown that there are about 7 of these children born per year per 100,000 of population. Further statistics demonstrate that of these 7, 1 dies during infancy or early childhood, so that the problem is of 6 new cases per year per 100,000 population. Of these 6, 2 will be definitely mentally defective. There is, therefore, a problem of 4 children per year per 100,000 population who will live and who are mentally deserving of rehabilitation. From this figure, the number of cases in any city or state under a given age can be easily computed. For example, in a city of 150,000 people there would be 6 of these children per year, under 16 years of age this would represent 96

mentally normal cases. Of these, it would be found that approximately 50 per cent are of moderate degree of severity, while 25 per cent would be mild and 25 per cent, severe.

Since cerebral palsy is a group of conditions, some sort of classification is necessary. An etiologic classification is not feasible, since congenital anomalies, birth injury, disease—such as encephalitis—trauma, and tumors could all give an identical picture if the location of the lesion were the same. An anatomic and pathologic classification is of great importance to pathologists and neurosurgeons, but since at present the detailed physiology and cerebral localization of function is so obscure this is chiefly of experimental value. It would seem, therefore, that if a classification on a basis of the type of motor disturbance could be made the various forms of therapy applicable to these conditions could be better evaluated.

Here, one is faced with a mass of loosely defined terms which have in the past confused the picture badly. On the one hand, there are spasticity, plastic and decerebrate rigidity, hypertonus, and hypercontractility, none of which are necessarily quite the same thing and may have origin in totally different parts of the brain. On the other hand, there are athetosis, chorea, choreo-athetosis, dystonia, ataxia, and many others that seem to overlap.

In order to arrive at a fundamental concept it is necessary to determine what possibilities there are for difficulties with muscle control. Obviously, aside from normal voluntary contraction, considering first the individual muscle, there can be inability to contract the muscle at all, which is usually flaccid paralysis. But this is complicated by the fact that there are muscles that cannot be contracted at all but are not necessarily flaccid. The opposite of this condition of paralysis or inability to contract a muscle voluntarily is, of course, a muscle that contracts involuntarily. The terms "flaccid" and "spastic" are opposites in reference to tone but not in reference to contractile power, either voluntary or involuntary.

It is necessary to distinguish, therefore, between variations in tone and variations in contractile ability, and these two are not always related. Of course, there are many combinations. In the ataxic extremity there often is flaccidity but no paralysis combined with involuntary motion of muscles not related to the act being performed. Also, true spasticity represents definite hypertonus with normal voluntary contractile ability. The

apparent difficulty with contraction of a true spastic muscle is the spasticity of its antagonist. The hypertonus is only evident upon contraction or other stimulus such as stretching.

Suppose only one of a pair of antagonistic muscles was spastic—the flexor spastic—the extensor being normal. Then it would be found that *flexion* could be normally performed, since the spastic flexor has normal contractile ability. *Extension*, however, performed by the normal extensor muscle would be the motion interfered with, since the hypertonus of the spastic muscle would be difficult to stretch. In fact, this very stretching sets up a reflex contraction of the muscle tending to block the motion attempted. This is the stretch reflex. If both the flexor and extensor were spastic, then motion would be impeded in both directions. The presence of the stretch reflex is the indication that a muscle is spastic.

By carrying out a muscle examination and determining which muscles show stretch reflex, the exact limitations of gait, arm use, and even speech can be determined. Unless this stretch reflex is present, true spasticity is absent. In rigidity, the hypertonus is constant and is of a plastic rather than a contractile type.

Involuntary motion is an entirely different category. In true athetosis there is no change in tone but only involuntary contraction taking place. The patient has no disturbance of his voluntary motor ability, but the results of attempted motions are distorted by the involuntary motions present. The pictures, therefore, of spasticity and athetosis would seem to be clear and distinct from each other, but as a matter of fact they are often confused. The reasons are these:

Attempted motion in the spastic sets up a stretch reflex as has been described. Suppose a spastic makes a voluntary attempt to extend the great toe. This motion causes a stretch reflex in the flexors of the toe, tending to pull it down. This, in turn, pulls down the foot, since the toe flexor is a long muscle arising high in the calf. This motion stretches the dorsiflexors of the foot pulling it up. This, in turn, stretches the gastrocnemius, which, being attached above the knee, tends to flex the knee, which stretches the quadriceps, extending the knee again. Since the quadriceps is also a hip flexor, through the action of the rectus femoris the hip is flexed, which stretches the gluteus maximus extending the hip. Thus, a whole train of motions is set

up in the leg simply as the result of the *voluntary* attempt to extend the great toe. It can easily be seen how much this might resemble true athetosis. The important observation is that the involuntary motion was initiated by a *volitional* attempt.

The athetoid can also closely resemble the spastic. If a normal individual riding in the back seat of an automobile being driven rapidly over a rough road was given a pad and pencil and asked to draw a straight line, the result would be discouraging. He would seize the pad, grip the pencil, and tense his hands and arms in an attempt to stop the motions. By so doing, however, all the jars would be carried to his hands, and the line being drawn would show it. Of course, if he should relax his whole body and loosen his hands, he could do much better, yet this would not be his natural tendency. The athetoid does the same thing. In an attempt to control the involuntary motions, early in life he tends to tense himself, and gradually this tension becomes habitual. The resulting picture is often stiff and rigid and strongly suggests the spastic. The important observation here is that the tension is *voluntary*, although habitual, and that the basic involuntary motions are not initiated by a *volitional* attempt. Thus, in the spastic the tension is *involuntary* and motion is *voluntarily* initiated, while the athetoid's tension is *voluntary* and the motion *involuntary*.

As was stated, the motor manifestations are the most obvious evidences of cerebral palsy and the ones from which the conditions get their names. The sensory disturbances are of considerable importance and are often overlooked. The eyes may be normal as far as visual acuity, myopia, hyperopia, or astigmatism are concerned, yet the extraocular motor control may be so disturbed as to make reading almost impossible. Strabismus of a spastic nature will result in monocular vision, since each eye can sometimes be moved easily in one direction and only with difficulty in the other. Thus, one eye would be used reading from left to right while the other would bring the fixation back to the beginning of the next line. The involuntary motions of the extraocular muscles seen in athetosis are sometimes such that there is limitation of upward and downward movement and, in other instances, of horizontal movement. Since these motions are frequently associated with athetoid motions in the neck, fixation on reading is difficult. These children can often fix on a single letter

or point but are unable to move along the line. Also, there is often nystagmus present which may blur the words or produce a sense of dizziness and nausea on attempting fixation. These children are best taught to read at a distance first, but only too often are these eye difficulties overlooked entirely, and the child's failure to learn to read is attributed to mental deficiency.

In the athetoid group especially, there is a definite incidence of hearing defects which again does not often show up on the usual hearing test. The child would be able to hear a pin drop or a watch at the normal distance from the ear, yet he will have a hearing loss or cutoff at a certain pitch level so that some of the sounds in normal speech will not be heard. This may cause a loss of the "S-F-T-H" group or, if the cutoff is lower, it may even involve the loss of the overtones necessary to the sound of the vowel "E." Then the words "seat," "set," "sit," "sat" would all sound to him like "uh." Since the "S" and "T" would not be heard and the "E" overtones are lost, his response to commands to say these words would all be "uh" and, since we all speak as we hear, his speech would be defective. Naturally, he would also have great difficulty in understanding speech.

Evaluation of mentality must take into consideration the possibility of these handicaps as well as the more obvious motor disturbances. There are, of course, true defects among the cerebral palsies, but the diagnosis of true mental deficiency must be made only after excluding all the disturbances of acquisition of knowledge through the eyes and ears and the disturbances of the demonstration of knowledge through the motor system, including speech. Speech may be absent or defective either because of defective hearing or because of spasticity or athetosis in the speech mechanism. Sometimes there are both a hearing defect and athetosis in the speech mechanism.

The presence of athetosis in the face, with grimaces and drooling, is misleading, and spastic facial muscles give an unresponsive expression. It must be borne in mind that these may be, in reality, masks and bear no relation to the underlying mentality. Cerebral palsy, therefore, represents multiple handicaps in the sensory, motor, and sometimes mental fields. The treatment must take into consideration all of these fields, and their importance must be evaluated.

In the motor field alone there are four chief considerations. These are locomotion (legs),

self-help (arms), speech, and general appearance. A severe case may be unable to use the arms or legs or speak. In this case the development of speech would change the entire outlook. Even if the arms and the legs were involved, then rehabilitation of the arms for self-help is much more important than locomotion. A mild case with only facial grimaces may find it more difficult to obtain employment than one who cannot walk. In other words, the degree or severity of involvement is not an indication for or against treatment. Low mental level may not always be a contraindication either, since, if a child can be taught to walk and feed himself, a great load may be lifted from the family. The true indications practically always depend upon the individual case. Formal speech training would be of one type if deafness were the cause, another type if the trouble was based on spasticity, and still a third type if the condition were athetoid in nature. The lack of speech might also be due to true aphasia, with damage to the speech center, or to actual mental deficiency. It is usually necessary for speech therapists to have additional training in cerebral palsy if they are to obtain satisfactory results.

The treatment of *true spasticity* in connection with the extremities is largely orthopedic. Motor re-education, aided by surgery and braces, is in general quite satisfactory provided a careful evaluation is made of the distribution of the spasticity by a muscle examination. As a result of this, it will be found that there are spastic, normal, and flaccid muscles present. The relationships of these to each other are extremely important. *The determination of the proper procedure on a spastic muscle depends entirely on the condition of its antagonist.* The orthopedic surgical methods include neurectomies, tendon lengthenings, tenotomies, myoneurectomies, transplants, and bony operations—such as stabilizations, bone blocks, tibial tubercle transplants—and other related procedures. Re-education both before and after surgery is imperative.

The treatment of involuntary motion or athetosis is entirely different. Here, surgical methods are absolutely useless, unless for true contractures. The reason for this is that athetosis is not related to individual muscles but is an attempt to perform a definite joint or series of joint movements with whatever muscles are available. This can be proved by blocking out athetoid pronation of the hand, for example, by means of a brace. The

result will be internal rotation of the shoulder. The results of both muscle-nerve operations and bone stabilizations performed on athetoids have borne this out.

The fundamental principle in the control of athetosis is training in relaxation as a skill and, subsequently, training in motion from the relaxed position. The relaxation must be thoroughly learned and must be complete throughout the body. This usually takes several months to acquire, even in the hands of the most skilled teachers. The surgery that is useful is such as that on the brain cortex (Klemme), the basilar mechanism (Meyers), and the lateral columns of the cervical cord (Putnam). These procedures give some promise for the future but are still in the experimental stage.

The treatment of the ataxic group may be described as a cortical retraining to replace the damaged automatic, usually cerebellar, and other balance functions. The use of drugs is not of great importance, since their effects are temporary and disappear when the effects of the drugs wear off. Curara, apart from its difficulty with standardization, has been said to paralyze the neuromuscular junctions of athetoid muscles before affecting the normal ones. But since athetosis varies even with gravitational factors, this statement would seem untenable. Certainly, there has been no striking effect seen so far.

The barbiturates and other relaxants such as alcohol have an unquestionably excellent effect, but the swingback, when the drug effects have worn off, is usually more marked than the normal degree of athetosis. The advantages of voluntary relaxation over drugs are great.

In all cases treatment must be thorough and not hurried. As yet there are no short cuts. Graphic records of improvement should be kept on all cases treated to determine the effectiveness of the treatment given and to determine as well the prognostic possibilities of the patient. The results obtained can be gratifying in a large percentage of cases when a collaborative effort is made by all the special fields of medicine which have a bearing on the condition.

Summary

1 The cerebral palsies are a group of conditions resulting from congenital, traumatic, disease, neoplastic, or degenerative causes.

2 The most useful classification for therapeutic purposes is a physiologic one.

3 Sensory handicaps are frequently associated with the motor disturbance and are of such a nature that they are often overlooked

4 True mental deficiency is present in some cases, but this must be determined only after thorough consideration of the effects of all the motor and sensory handicaps

5 Treatment lies mainly in the re-educational and surgical fields and is effective in a large proportion of cases when carried out intensively

3038 St. Paul Street

Discussion of Symposium

Dr Robert Lee Patterson, Jr., *New York City*—Dr Duryea's excellent report emphasizes the prevalence of infantile cerebral palsy as a crippling condition and the extent to which attempts are being made to meet its various needs. A great part of the progress that has recently been made in this work is due to the efforts of Dr Phelps. He has once more brought out points that tend to clarify the subject and give us a better understanding of therapeutic handling and care.

Any one of us who has had experience in the care of cases of cerebral palsy has discovered that surgery on the athetoid type is, as a rule, useless and may even prove harmful, except where definite contractures that act as mechanical hindrances have formed. Dr Phelps's explanation of the physiologic processes occurring in athetoids and spastics shows us why surgery should not be performed on the athetoid without serious consideration. Since orthopedic operations in the true spastic are helpful, often dramatically so, it is extremely important to be able to distinguish between athetosis and spasticity. Certainly, Dr Phelps has most clearly presented to us the known facts on this subject.

Advancements in the early diagnosis and treatment of cerebral palsy have been marked during the past ten years. Undoubtedly, the majority of the steps forward have been in the line of care, re-education, schooling, and appreciation of pathologic physiology. However, there has also been considerable stimulus and progress from the orthopedic surgeon's standpoint. Because of better follow-up systems, we have been able to find out the results on various types of operations and we have been able to evaluate their merits and to formulate a reasonable operating policy. Several new operations have been devised which, with the passage of time, continue to prove beneficial.

Formerly, for adducted, internally rotated thighs, we did a resection of the nerves to the adductors and a tenotomy of the adductor longus and also of the other adductors if they seemed tight. Between 1926 and 1936, 103 of these operations were performed at the Hospital for the Relief of the Ruptured and Crippled (the

Hospital for Special Surgery). In a follow-up survey, only 80 of these were classified as good, there were many recurrences. In the last five years we have been cutting the obturator nerves where they exit from the pelvis (Selig operation), not touching the adductor muscles. Out of 73, only 2 have been rated as poor, both having also a bilateral congenital dislocation of the hip.

An analysis of 85 cases that had a lengthening of the tendo achillis showed that there was a recurrence of the equinus position in 57. This operation is now supplemented by a foot stabilization or a bone block with foot stabilization. The results have been most gratifying.

An observation that has proved to be of great value to the orthopedic surgeon is that of Chandler who shows that often the transplanting of the biceps femoris into the extensor group at the knee is not successful because of the relaxation and stretching of the patella tendon and that extension would be possible if this relaxed tendon were made taut.

For the extreme case of athetosis, marked improvement and subsidence of the involuntary movements of the neck and extremities have been accomplished by the section of the extrapyramidal pathways, as performed by Dr Putnam. Although we have had no personal experience with this operation at our hospital, I have seen some of Dr Putnam's cases and results and can assure you that the procedure is a most helpful one.

On the basis of a more exact evaluation of facts regarding cerebral palsy obtained during the past ten years, we have made a grouping of the indications for performing surgery on these cases, fully appreciating the fact that surgery serves only as an adjunct in the treatment of the spastic. We have found surgery to be indicated:

1 When there is a fixed contracture or bony deformity that will obviously prevent the patient from performing exercises properly.

2 When, after a period of six months to two years, training has reached a standstill and static deformities have developed, such as a pronated forearm or an equinovarus foot.
